Mr. Bevan emphasized that the highest ethical standards must be demanded from the public and the medical professions if the Health Service is to be a success, when he addressed the first annual meeting of the Executive Councils Association on Oct. 7. Because things were free there was no reason why people should abuse their opportunities, he said. That was a very great test of the maturity of the British people. If any individual abused the opportunities he must reckon with a sum total which might add up to one too grievous to carry and for which it would be very difficult to continue to provide. The general practitioner had a very great responsibility. Over-prescribing could be as bad as under-prescribing. He was gratified that 18,165 general practitioners had joined the Service and that 92% of the population of about 42,500,000 were now on doctors' lists. The total was increasing daily, and he expected that by the end of the year practically all would be participating in the scheme. Over 80% of dentists were in, by Sept. 17, 1,000,000 people had sought dental treatment under the scheme. Prescriptions were dispensed at the rate of about twice that under the N.H.I. scheme. If the rate were maintained it would mean that 140-150 million prescriptions would be dispensed annually under the scheme. Mr. Henry Lesser was elected president, and Dr. N. E. Waterfield vice president.

Sir William Marshall, president of the Scottish Association of Executive Councils, speaking on Oct. 8 thought that the idea had crept into the minds of a proportion of the population that while they were contributing a substantial sum weekly they should get some return in the way of dentures, glasses, or prescriptions. He doubted whether all the spectacles demanded were really required. Mr. W. T. Shanks, chairman of the Birmingham Council, moved a resolution protesting against the ruling that doctors practising at health centres would not be permitted to treat private patients there. Dr. A. Beuchamp seconded it. Dr. N. Graham, of West Hartlepool, said that it was not within the power of the Minister to depart from the N.H.S. Act. The motion was defeated by 105 votes to 76.

## Colonial Medical Research Studentships

A limited number of research studentships will be awarded on the advice of the Colonial Medical Research Committee to graduates in medicine and cognate sciences who wish to prepare for research work in tropical medicine and related subjects. The studentships are tenable at any university or other institution approved by the committee, a maintenance allowance being paid. A studentship will normally be awarded for two years subject to a satisfactory report after one year. Candidates should be British subjects and graduates of British universities, and those completing their courses will be offered posts in the projected Colonial Research Service. Applications should be made through the head of the candidate's department to the Secretary Colonial Medical Research Committee, c/o Research Department, Colonial Office, Sanctuary Buildings, Gt. Smith Street, London S.W.1, and should include details of the candidate's academic record and an indication of the subject preferred.

## WHO Conference

A conference of Government representatives from war-devastated countries in Europe will be held under the auspices of the World Health Organization in Geneva on Nov. 15 and 16. The representatives will discuss the establishment of a temporary administrative office to assist the rehabilitation of their countries and the kind of services that their countries need.

## Drinks Not Drugs

The National Pharmaceutical Union has sent out a memorandum reminding its members that the Ministry of Health does not regard whisky, brandy, and other spirits, wines, beer, and stout as drugs which can be supplied under the National Health Service.

## Collection of Type Cultures

The Medical Research Council published on Oct 15 a *List of Species Maintained in the National Collection of Type Cultures*. This list is not intended to be a substitute for the *Catalogue of the National Collection of Type Cultures*, which was last revised in 1936 and is now out of print but the new edition of the *Catalogue* will take several years to prepare and meanwhile bacteriologists may wish to know what species are available at the National Collection and how many strains of each species are maintained. The information given in the list is correct to the beginning of June, 1948. This new Memorandum (No 21) can be obtained from H M Stationery Office price 9d.

## Norman Gamble Fund of R S M

The Norman Gamble Fund provides grants in aid of research work in otology. The committee of award will consider applications in December. These should be received not later than Nov 25 by the secretary, the Royal Society of Medicine, 1, Wimpole Street, London, W1. The grants may be awarded to any British subject, lay or medical recommended by the committee of award, or to a research institute selected by the committee.

## COMING EVENTS

## Hunterian Society

The 1948-9 programme of the Hunterian Society has been arranged as follows: Monday Oct 18, 7 for 7.30 p.m., at Talbot Restaurant, 64 London Wall, E.C., dinner, special general meeting, and presidential address by Dr G R Mather Cordner on "The Role of Radiology in Relation to the Peptic Ulcer Problem", Monday Nov 15, 8.30 p.m. at Society of Apothecaries of London, Black Friars Lane, Queen Victoria Street E.C., discussion "That the Practice of Instructing the Layman in the Nature and Treatment of Disease is being Carried to Excess" to be proposed by Dr W J O'Donovan and Miss Arnot Robertson and opposed by Dr Charles Hill and Miss Bronwen Lloyd Williams, Monday, Dec 20, 7 for 7.30 p.m., at Talbot Restaurant, dinner and discussion on "Toxic Jaundice," to be opened by Professor John McMichael and Dr Alice M Stewart, Monday, Jan 17, 8.30 p.m., at the Mansion House, London E.C., Hunterian Lecture by Dr John M Finney, jun (Baltimore), on "The Founding and Influence of a School of Surgery", Thursday, Feb 10 at Grosvenor House, Park Lane, London, W., annual dinner, Monday Feb 28 8.30 p.m., at the Mansion House Hunterian Oration by Sir Heneage Ogilvie on "Personal Experiences", Monday March 21, 7 for 7.30 p.m., at Talbot Restaurant, dinner and discussion on "The Treatment of Coronary Thrombosis" to be opened by Dr William Evans, Dr Geoffrey Bourne, and Mr George A Mason, Monday, April 25, 7 for 7.30 p.m., at Talbot Restaurant dinner and address by Mr Cortlandt MacMahon on "Speech Defects and Voice Affections".

## West London Medico Chirurgical Society

The West London Medico Chirurgical Society will hold a dinner at the South Kensington Hotel, 41, Queens Gate Terrace, London, S.W.7, on Friday, Oct 22, at 7.15 for 7.30 p.m. The presidential address will be delivered by Dr W S C Copeman at 8.30 p.m. on "West London Worthies—A Retrospect".

## Long Fox Memorial Lecture

The thirty-seventh Long Fox Memorial Lecture will be delivered by Professor R Milnes Walker in the Large Physics Lecture Theatre (Royal Fort) University of Bristol, on Tuesday, Oct 19, at 8.15 p.m. His subject is "Some Aspects of Hospital Economy". Admission to the lecture is free.

## Donald Gillies Lecture

The Donald Gillies Lecture arranged by the National Marriage Guidance Council will be delivered by Miss Phyllis Bottomo, the novelist and biographer of Alfred Adler, on "Love and Marriage," at the Royal Society, Burlington House, London, W1 on Oct 20 at 6 p.m. The chair will be taken by Sir Eardley Holland.

## Honman Gillespie Lectures

A series of Honman Gillespie Lectures has been arranged in association with the Edinburgh postgraduate courses to be given in the West Medical Theatre of Edinburgh Royal Infirmary on Thursdays at 5 p.m. from Oct 21 to Nov 25 both dates inclusive. The lectures are open to all graduates and senior students. Details will be published weekly in the diary column of the *Journal*.

## Parentcraft in the Home

A conference on "Parentcraft in the Home" has been arranged by the National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality, to be held at Queen Mary Hall, W.C.A. Buildings, Great Russell Street, London, W.C.1 on Friday, Oct 22 at 10.30 a.m. under the chairmanship of Dr Leslie Housden. Admission is free by programme obtainable from the secretary of the association at 5 Tavistock Place, London, W.C.1.

## Lecture-demonstrations on Neurology and Psychiatry

A series of lecture-demonstrations on neurology and psychiatry began at St George's Hospital Medical School Hyde Park Corner, London, S.W., on Oct 7 and will continue on Thursdays, at 4.30 p.m., until Dec 16. The lecture demonstrations are open, without fee, to all medical practitioners and senior medical students.

## Course on Chronic Rheumatic Diseases

A concentrated week-end course on the chronic rheumatic diseases will be held on Oct 23 and 24 at the Rheumatism Unit, St Stephen's Hospital, 369, Fulham Road, London, S.W. The course will consist of lectures, ward rounds, and practical demonstrations, including orthopaedic and manipulative methods of treatment. Sir Adolphe Abrahams will give the inaugural address. Applications to attend the course should be addressed to the Fellowship of Postgraduate Medicine, 1, Wimpole Street, London, W.1.

## British Orthopaedic Association

The annual meeting of the British Orthopaedic Association will be held in Belfast on Oct 21, 22, and 23, under the presidency of Mr S A S Malkin, F.R.C.S.Ed.

## Monmouthshire Medical Golfing Society

The autumn meeting of the Monmouthshire Medical Golfing Society will be held at Pontypool Golf Club on Sunday, Oct 17. At 10 a.m. a tankard competition will be played, medal play under handicap (18 holes), and at 2 p.m. there will be a four ball competition.

## Nurses Conference

The thirty-third Annual Professional Nurses and Midwives Conference will be held on Oct 18-22 at Seymour Hall, Seymour Place, London, W.1, under the auspices of the *Nursing Mirror*. The conference and exhibition are open only to nurses, midwives, and medical practitioners and auxiliaries.

## SOCIETIES AND LECTURES

## Monday

HUNTERIAN SOCIETY—At Talbot Restaurant 64, London Wall, E.C., Oct 18, 7 for 7.30 p.m. Dinner special general meeting. *The Role of Radiology in Relation to the Peptic Ulcer Problem* presidential address by Dr G R Mather Cordner.  
ROYAL COLLEGE OF PHYSICIANS OF LONDON—Pall Mall East, S.W.—Oct 18, 3 p.m. *The Structure of Medicine and its Place among the Sciences* Harveian Oration by Dr F M R Walshe F.R.C.P. F.R.S.  
SOCIETY OF APOTHECARIES OF LONDON—In the Hall, Black Friars Lane, Queen Victoria Street E.C. Oct 18 3 p.m. *The Clinical Importance of the Rh Factor* by Professor D F Cappell.  
UNIVERSITY COLLEGE—Gower Street W.C.—Oct 18 4.45 p.m. *The Electron Microscope and its Biological Applications* by Dr E M Crook, M.Sc. Ph.D.

## Tuesday

BRISTOL UNIVERSITY—LARGE PHYSICS LECTURE THEATRE (ROYAL FORT)—Oct 19 8.15 p.m. *Some Aspects of Hospital Economy* thirty-seventh Long Fox Memorial Lecture by Professor R Milnes Walker.  
INSTITUTE OF DERMATOLOGY, 5 Lisle Street Leicester Square, London, W.C.—Oct 19, 5 p.m. *Popular Dermatoses* by Dr F Ray Bettley.  
INSTITUTE OF LARYNGOLOGY AND OTOLGY 330-2, Gray's Inn Road, London W.C.—Oct 19 2.30 p.m. *Malignant Diseases and Radiotherapy* by Mr W A Mill.  
SOCIETY OF APOTHECARIES OF LONDON—In the Hall, Black Friars Lane, Queen Victoria Street E.C. Oct 19 5 p.m. *Reliability of the Physically Injured* by Mr H O Clarke.  
SOCIETY FOR THE STUDY OF ADDICTION—At Medical Society of London 11 Chandos Street W. Oct 19, 4 p.m. *Some Advances in the Treatment of Anxiety and Addiction by Apomorphine* by Dr J Yerbury Dent. A discussion will follow.

## Wednesday

GLASGOW UNIVERSITY—DEPARTMENT OF OPHTHALMOLOGY—Oct 20 8 p.m. *Plastic Surgery of the Eyelids* by Dr Byron Smith.  
HARVEIAN SOCIETY OF LONDON—At 26 Portland Place London W. Oct 20, 8.15 p.m. *Pulmonary Embolism* by Dr Samuel Oram.  
ROYAL INSTITUTE OF PHILOSOPHY—At University of London Institute of Education, Malet Street, London W.C. Oct 20 5.30 p.m. *Decline or Revival of Religion* by Rt Hon Viscount Samuel.  
ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE 28 Portland Place London W.—Oct 20, 3.30 p.m. *Epilepsy in Children* by Dr Petr Henderson.  
SCOTTISH SOCIETY OF THE HISTORY OF MEDICINE—At Royal Faculty of Physicians and Surgeons of Glasgow 242 St Vincent Street, Glasgow Oct 20 5.30 p.m. *The History of Glasgow* by Professor J D Mackie. *The History of the Royal Faculty of Physicians and Surgeons of Glasgow* by Mr A L Goodall.  
SOCIETY OF APOTHECARIES OF LONDON—In the Hall, Black Friars Lane, Queen Victoria Street E.C. Oct 20 5 p.m. *Modern Treatment of some Neurological Disorders* by Dr Macdonald Critchley.

## Thursday

- DREADNOTHT SEAMEN'S HOSPITAL, Greenwich, S E.—Oct 21, 3 p.m.  
Clinical demonstration by Messrs S Power and L Lurie
- EDINBURGH CLINICAL CLUB, Drumsheugh Gardens, Edinburgh—  
Oct 21 8 p.m. *The Family Position* by Dr G W Ireland
- EDINBURGH ROYAL INFIRMARY—Oct 21, 5 p.m. *Intracranial Tumours in the Aged* Honyman Gillespie Lecture by Mr Joe B Pennybacker
- ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE 26, Portland Place, W.—Oct 21, 7.30 p.m. *The Epidemiology of Fungus Diseases* by Dr J T Duncan, *The Treatment of Fungus Diseases* by Dr Isaac Muende Discussion
- ST GEORGE'S HOSPITAL MEDICAL SCHOOL Hyde Park Corner, London, S W.—Oct 21 4.30 p.m. *Neurology and Psychiatry* Lecture demonstration by Dr Anthony Feiling
- SOCIETY OF APOTHECARIES OF LONDON—In the Hall Black Friars Lane Queen Victoria Street, E C, Oct 21, 5 p.m. *The Treatment of Pulmonary Tuberculosis* by Dr R R Trail

## Friday

- MIDDLESEX COUNTY MEDICAL SOCIETY—At Hillingdon Hospital Uxbridge, Oct 22, 3 p.m. Clinical cases *A Report on 450 Caesarean Sections*, by Dr Joyce Morgan *Carcinoma arising in Segmental Bronchi* by Mr K S Mullard
- ROYAL INSTITUTE OF PHILOSOPHY—At University Hall, 14, Gordon Square, London, W C, Oct 22 5.15 p.m. *The Present State of Moral Philosophy* by Arthur MacIver M A
- ROYAL SANITARY INSTITUTE—At Poole Municipal Buildings Oct 22 10 a.m. *Food and Health* by Lord Llewellyn, *Food and Disease* by Dr G J G King, *The Chlorination of Sewage Effluents* by Mr R Leggat

## APPOINTMENTS

- BAIRD I MCL MB ChB Clinical Assistant to the Medical Unit Sheffield Royal Hospital
- BUNTING F W MBE, MD ChB DPH Medical Officer of Health for Widnes
- EASTWOOD C G BSc MD ChB MRCS LRCP DPH Medical Officer of Health Cambridge
- HAND B J MB BCh BAO NUI Deputy Medical Superintendent to the Mid Wales Counties Mental Hospital
- MIDDLESEX HOSPITAL London W—*First Assistant Professorial Surgical Unit* R S Monro MB BCh FRCS *Acting Otolological Registrar* S Kavanagh FRCS Ed DLO
- MURRAY J O MD, MB ChB DPH Joint Medical Officer for Rochester and Chatham
- SLEIGH J C MB ChB DPH Divisional Medical Officer for St Albans
- WILLIAMS T G MRCS LRCP Psychiatric Physician to the North Wales Counties Mental Hospital

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTHS

- Evans—On Oct 3 1948 at Bath to Joan wife of Dr David Trevelyn Richard Evans a daughter
- Hart—On Oct 5 1948 at Westminster Hospital S W to the wife of Dr F Dudley Hart a daughter
- Murphy—On Oct 9 1948 to Drs Mary Patricia (née McHugh) and Grabame Edward Murphy a daughter
- Wolfson—On Oct 3 1948 to Nancy wife of Dr L J Wolfson a daughter

## MARRIAGES

- Crook—Lockhart—On Sept 25 1948 David Crook MRCS LRCP of London to Ellen Lockhart SRN of Middlesbrough

## DEATHS

- Aubrey—On Sept 30 1948 after a short illness Harold Percival Aubrey MRCS LRCP LDS Eng of 1 Down Cottages Lansdown Bath
- Blake—On Sept 24 1948 at University Square Belfast Eric Oliver Blake MB BCh BAO
- Cameron—On Sept 26 1948 at Kingarth Fortrose John Cameron MB CM JP
- Cookes—On Sept 22 1948 Reginald Vincent Cookes L M S S A of Penybryn House Brynhyfryd Swansea
- Cosgrave—On Sept 30 1948 suddenly Frederick Robert Cosgrave MD of Offham Manor West Malling Kent
- Easton—On Sept 24 1948 William Cochrane Cairne Easton MB ChB of 23 Henley Avenue Ilfley Oxford and late of Cleveleys Lancashire
- Fisher—On Sept 25 1948 at Woodford Barnton Midlothian Edward Fow Fisher FRCS of Edinburgh
- Garrand—Found dead in his surgery in High Street Linlithgow on Sept 23 1948 Andrew Ford Garrand LRCP & S Ed L R F P S Glas
- Gavronsky—On Sept 24 1948 Jacob Osep Gavronsky MD of SS Netherhall Gardens NW aged 70
- Ghosh—On Sept 24 1948 at Salford Royal Hospital Jotindranath Ghosh FRCSI agd 61
- Owen Prehard—On Sept 21 1948 at King Edward VII Hospital Windsor William Owen Prehard LRCP & S Ed L R F P S Glas Lieutenant Colonel R A M C
- Patterson—On Sept 19 1948 George de Joncourt Patterson MD of Lechlade Gloucestershire aged 91
- Pillans—On Sept 24 1948 at 14 Aytoun Road Pollokshields Glasgow Annie Fleming Pillans LRCP & S Ed L R F P S Glas

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

## Spondylitis and Kyphosis

Q—What is the modern classification from the aetiological point of view of (a) spondylitis and (b) kyphosis? Have the old terms von Bechterew's disease and spondylose rhizomelique of Strumpell-Marie become obsolete? Is there any relation between the Scheuermann Calve osteochondritis and spondylitis? What is the nature of the very pronounced kyphosis in relatively young and fairly active people which one sees not uncommonly where the spine is almost a segment of a not very large circle? Is this condition progressive and how does it end?

A—The term *spondylitis* strictly implies an inflammatory condition of the vertebral column. Aetiological it may be classified into three main types as follows: (1) tuberculous spondylitis, (2) pyogenic spondylitis, (3) ankylosing spondylitis. By customary usage however, spondylitis has come more and more to imply ankylosing spondylitis, the other two conditions being termed simply tuberculosis of the spine and pyogenic osteomyelitis of the spine respectively. The term spondylitis (or spondylolysis) deformans is sometimes used to describe deforming conditions of the spine from any cause. As it does not refer to any specific disease entity the name leads to confusion and should be discarded. Osteoarthritis of the spine should not be referred to as spondylitis, for it is a non-inflammatory degenerative condition similar to osteoarthritis elsewhere.

Kyphosis is classified on an aetiological basis into the following groups: (1) congenital (e.g. congenital wedged vertebra, gargoyleism, etc.), (2) postural, (3) traumatic (e.g. compression fracture), (4) inflammatory (e.g. tuberculous or pyogenic infection), (5) neoplastic (primary or secondary), (6) generalized bone disease (e.g. rickets, senile osteoporosis), (7) miscellaneous conditions (e.g. osteochondritis of Scheuermann type, Calve's disease).

The name ankylosing spondylitis is now used to describe the condition which was formerly widely known as spondylitis rhizomelique or as spondylitis of Marie-Strumpell type. These latter terms, though still in use at some centres have been largely discarded by British surgeons. Similarly the term 'spondylitis of von Bechterew type' formerly used to describe osteoarthritis of the spine, has been discarded in this country. There is no relation between Scheuermann's osteochondritis and ankylosing spondylitis.

A pronounced rounded kyphosis occurring in relatively young subjects is likely to be due to one of two conditions. The first and less disabling is osteochondritis of Scheuermann type, often referred to as adolescent kyphosis. This condition may lead to wedging of the lower dorsal vertebral bodies, with well-marked rounding of the spine. It is not a progressive condition although the altered shape of the affected vertebrae may predispose to the development of osteoarthritic changes in later years. The second possibility is ankylosing spondylitis. This leads to marked rigidity of the spine extending from below upwards, and may progress ultimately to solid bony fusion of the entire spinal column; the hips and shoulders are also not infrequently affected. The stiffness is in some cases associated with a fixed kyphosis so severe that the patient is able to look only towards his feet.

## Hyperemesis Gravidarum

Q—What is the latest treatment of the severe disabling type of nausea and vomiting of early pregnancy?

A—The present-day treatment of hyperemesis gravidarum is not very different from that practised twenty years ago, although there is a change in emphasis in that much attention is paid to combating the acidosis which results from vomiting but which in turn causes more vomiting. Various remedies, including most of the vitamins have been tried, but none have proved

specific. It is essential to admit the patient to hospital and isolate her from all her relatives and from other patients, this is enough to cure a large proportion of cases. If vomiting persists in spite of hospital regime and frequent small meals of a fat free nature tried for twenty four hours, the oral administration of both food and fluid is discontinued and 5% glucose in saline is given by continuous intravenous drip. Acetonuria nearly always calls for intravenous glucose therapy. Such treatment gives good results: the dehydration and acidosis are usually overcome within twenty four hours and vomiting ceases. Accessory treatment with vitamin B<sub>1</sub> and calcium gluconate (both by injection) is usually given. Some also administer small doses of insulin, but this is not really necessary. When there has not been any vomiting for forty eight hours, oral feeding is cautiously resumed with dry toast or biscuits and small frequent drinks of glucose fluids or dilute milk. The ease with which intravenous glucose can now be given and maintained has considerably improved the outlook in these cases and termination of the pregnancy is rarely necessary.

### Prevention of Oil Dermatitis

**Q**—Is Dakin's solution used extensively by mechanics as a preventive against oil dermatitis? Is it effective? What are its chief uses to day and how does it compare with other similar solutions?

**A**—Dakin's solution has been advocated as a preventive of oil dermatitis but its value in this connexion has been limited by difficulties connected with its proper use, together with its corrosive action on metal containers. The solution does not, of course, remove dirt from the skin, and washing with soap and water should follow its use. In practice it was difficult to ensure that each machine operative had enough Dakin's solution properly diluted and for his individual use after work. As an oil emulsifier it was reasonably effective, and, since the solution oxidizes organic matter, the risk of sepsis was reduced. In industry a skin cleanser composed of neutral sulphonated castor oil with 1% of a wetting agent has largely taken the place of Dakin's solution for the removal of oil from the skin. It is in practice difficult to remove completely mineral oil from the skin and, while some measure of success may attend the use of alkaline detergents and of soapless cleansers, there is a tendency for these especially over long periods to cause excessive dryness of the skin. Sulphonated castor oil does not seem to produce this effect.

### Sexual Potency in Paraplegics

**Q**—I have heard recently of a drug injected intrathecally in paraplegics which relaxes muscle spasm and often results in ejaculation of normal semen. Is this curative? Is it feasible that a paraplegic after an injection would be able to have intercourse? Presuming the answer to be Yes does ejaculation occur at any fixed time after the injection and is there always an erection? Does the drug relax muscle spasm in all paraplegics no matter what the cause?

**A**—The drug in question is prostigmin. In a communication to the Physiological Society on Dec 6, 1947 L. Guttman reported on the effects of prostigmin after intrathecal injection in paraplegia due to spinal cord and brain injuries. While prostigmin undoubtedly acts as a depressant on the skeletal muscles, as found previously by Kremer Pearson and Wright (*J. Physiol.* 1937 89 21P), Guttman discovered a stimulating effect on the reproductive organs. About one to two and a half hours after intrathecal injection of 0.3 to 0.75 mg prostigmin he observed erections, followed in about 50% of the cases by ejaculations. In most cases investigation of the seminal fluid revealed motile sperms of normal appearance. Not in every case was ejaculation accompanied by erection, this was found with certain cauda equina lesions.

These findings disprove the widespread belief that paraplegics are sexually impotent and non-fertile. Certain types of paraplegics after intrathecal injection would be able to have intercourse provided there is full co-operation by the female partner. Where this is not possible artificial insemination could be tried. Unpleasant side effects in some cases following administration of prostigmin are vomiting and sweating. Prostigmin after intrathecal injection relaxes muscular

spasms in all paraplegics, no matter what the cause. However this depressant effect, which varies in intensity, lasts only six to eight hours.

### Sun bathing for the Adult

**Q**—Are there any medical reasons for the firmly held belief that sun-bathing is beneficial to the adult?

**A**—There is no objective evidence that sun bathing has any beneficial action in the normal adult. It must, however, be pointed out that people who sun-bathe usually do it because they enjoy it. The fact that it imparts a tan, which makes them look healthier and possibly more attractive according to present-day standards and also that it affords a pleasant form of rest, may account for the belief that sun bathing has some therapeutic value. But at the same time there is no evidence that individuals leading a conventional life are in any way less healthy than the sun-worshipping nudist, provided their diet and its vitamin D content are adequate. This does not mean that irradiation with ultra violet rays or any other form of radiation contained in sunlight has no therapeutic effect when indications for treatment with such radiations arise.

### Herpes after Coryza

**Q**—My daughter, aged 12 suffers from severe nasal labial herpes after every cold in the head however slight. Her mother and grandmother have the same trouble. It is four weeks since her last cold cleared up and she still has a large smooth naevus-like area between lip and nose on one side. Apart from long standing bronchial asthma she is healthy. Can you advise me about prevention and cure?

**A**—If there is any focus of infection or of irritation (as from an unerupted tooth) in the nose, throat, or mouth, removal of this may stop recurrences of the herpes. Otherwise the condition is often most resistant, but it sometimes responds either to fractional doses of x rays to the area affected or to shock therapy. A course of arsenic by mouth in increasing doses to tolerance occasionally stops recurrences, and in some hands vaccination with serum from a vesicle has proved helpful.

## NOTES AND COMMENTS

**Dangers of Cinchophen**—Dr G. H. JENNINGS (Edgeware Middlesex) writes: I was interested to read the letter from Dr Ewan F. B. Cadman (Oct 2, p. 668) on the subject of the cinchophen treatment of gout. It was because my views were very similar to his that some years ago I undertook a little investigation in which I compared the effect of 80 gr (5.3 g) daily of sodium salicylate and 45 gr (3 g) of cinchophen on eight cases of chronic gout. With the conditions as favourable as possible for a fair comparison I found that in six of the cases the average daily excretion of uric acid was greater with the sodium salicylate than with the cinchophen treatment, in five of the cases very appreciably so. In the other two cases one showed equal average daily excretion with the two drugs, the other showed a greater excretion with cinchophen. The figures can be seen in the *Reports on Chronic Rheumatic Diseases* (1937, No 3, p. 106). On the clinical side I felt that the improvement obtained with sodium salicylate treatment was certainly as good as with cinchophen. I also found some benefit from sodium salicylate in attacks of acute gout, and as it is a relatively non-toxic drug I would certainly recommend sodium salicylate as a "safer alternative" in the treatment of gout.

**"Harvesters"**—Professor H. E. ROAF (Liverpool, 19) writes: I have heard, and experience seems to confirm, that finely divided sulphur dusted on the skin—e.g. inside underwear and socks—prevents the attacks of 'harvesters'.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 16 1948

## British Medical Association

### REPORT OF INSURANCE ACTS COMMITTEE, 1948

#### Chairman

Dr E A Gregg was reappointed Chairman of the Committee for the Session 1947-8

#### Ministry of Health Distribution Committee

The Committee's nominees on the Ministry of Health Distribution Committee in connexion with the Central Practitioners and Mileage Funds are Dr E A Gregg (London), Dr D J B Wilson (High Wycombe), Dr D B Evans (Wrexham), and the Assistant Secretary (Dr L S Potter), together with Dr J A Pridham (Weymouth), Dr J C Pearce (Diss, Norfolk) and Dr J D Wells (Billericay) when questions concerning mileage are under consideration

#### Future Designation of Insurance Acts Committee

Local Medical Committees have already received a communication (July 12, 1948) announcing the decision to rename the Committee 'The General Medical Services Committee, and to leave unchanged, at the outset, the constitution of the new Committee. The election of the various groups of members is proceeding, and the new Committee will begin its work after the Annual Conference. It will probably review its constitution (including the grouping of areas for the election of direct representatives) in the light of experience, and will consider any proposals in this respect which Local Medical Committees or the Conference may wish to make

#### 1947 Conference Resolutions

Owing to the preoccupation of the Ministry of Health with preparations for the introduction of the National Health Service, and the brief period left before the termination of the NHI medical service, the Committee was unable to make progress on some of the matters which were discussed at the last Annual Conference. Included among them was the Ministry's attitude on the reference of patients to specialists after examination by a regional medical officer. This question is down for early discussion in its relation to administrative procedure under the National Health Service

Several of the Conference resolutions dealt with questions of principle relating to the National Health Service, and these are being borne in mind in negotiations with the Ministry of Health

#### Dispensing and Prescribing

**Capitation Fee for Emergency Drugs and Appliances**—As the result of representations by the Committee, the amount of the capitation fee for drugs and dressings required in an emergency before a supply could be obtained otherwise was doubled with effect from Oct 1, 1947. In 1938 the capitation fee in question varied between 1s 3d and 2s 6d per hundred insured persons the higher rate being paid in areas where the liability for emergency treatment was above the average

**Payments for Drugs supplied by Doctors in Special Circumstances**—The Committee was asked by the Ministry of Health

for its observations on a proposal to withdraw the payment of 'profit' on the ingredient cost when a doctor supplied drugs to an insured patient in certain circumstances. The Ministry was informed that the Committee was not in favour of any departure from the existing arrangements for payment in the case of (1) drugs in the special list supplied to dispensing patients, or in an emergency, and (2) drugs not in the special list but for which payment is specially sanctioned

**Specialty Expensive Drugs**—The Committee was successful in securing the addition of the following preparations to the list of expensive drugs appended to Part II of the Distribution Scheme: Mersalyl suppositories, Anti-histamine agents (covers "benadryl," "antistin," and "anthisan"), Vitamin E (covers ephyal)

**Increase of Purchase Tax on Certain Drugs**—In the autumn of 1947 the attention of the Ministry of Health was drawn to the effect of the increase in purchase tax on certain drugs on the overall cost of supplying medicines to insured persons for whom doctors were required to dispense. Subsequently, certain concessions were made which eased the position, and the Committee's claim for an increase in the dispensing capitation fee on this account was not pressed

#### Medical Records of Persons no Longer Entitled to Medical Benefit

It was the normal practice, when a person ceased to be entitled to medical benefit, for the person's medical record card to be withdrawn by the Insurance Committee and held for a period of three years to meet the possibility that the person might re-enter insurance during that period. The Ministry informed the Committee that it would not be practicable, under the National Health Service, to reissue records which had been withdrawn, and it was proposed to instruct Insurance Committees to destroy them at the appropriate time. The Committee reluctantly agreed, but asked that Insurance Committees be instructed at once not to withdraw from a doctor's possession any more record cards of persons coming out of insurance

#### Election of Local Medical Committees

Early in July every Local Medical Committee was urged to hold an election if it had not already done so. A model scheme the draft of which had been shown to the Ministry of Health was circulated to secretaries, and for the purposes of the National Health Service Act it can be assumed that the Minister will recognize every committee constituted in general accordance with the model scheme

An essential feature of the constitution of every Local Medical Committee is that it shall be representative of all the medical practitioners in the area

#### National Health Service

Anticipating that the first plebiscite would result in a large majority against service under the National Health Service Act

is it then stood the Committee decided at a special meeting in January to convene a Special Conference of representatives of Local Medical and Panel Committees to be held on the day before the Special Representative Meeting of the B.M.A. in March. The object of the Conference was to provide an opportunity for an expression of the collective views of insurance practitioners on the situation confronting the profession as a whole. The Special Conference was held on March 16 and the following resolution, similar in terms to that passed the following day by the S.R.M., was carried without dissent.

**11 Resolved** That this Special Conference of Local Medical and Panel Committees, reaffirming the whole-hearted desire of the medical profession for a comprehensive health service available to everyone, urges that in the public interest such changes should be made in the National Health Service Acts of 1946 and 1947 as are necessary to maintain the integrity of medicine and to prevent doctors being turned into State servants, with harmful consequences to patient and doctor alike. The Conference therefore expresses the hope that the Government will make it possible for the profession to co-operate by making such changes and states its view that it is not in the best interests of the public or of medicine for members of the profession to enter the Service until such changes are made.

**Matters dealt with by the General Practice Subcommittee of the Negotiating Committee**—The Negotiating Committee, at its meeting on May 20 1948 after a general discussion on future policy decided that future negotiations with the Ministry of Health should be conducted through the Negotiating Committee, and that continued membership of the Committee by the constituent bodies represented should be on the understanding that the Committee would undertake negotiations on behalf of the profession as a whole. After further discussion it was decided to appoint a number of subcommittees for the purpose of further negotiations with the Ministry on matters within their respective fields, subject to ratification of their activities by the full committee. Among the subcommittees appointed was a General Practice Subcommittee with the following personnel: Dr H. Guy Dain, Lord Webb Johnson, Dr J. C. Arthur, Dr J. A. Brown, Dr O. C. Carter, Dr R. W. Cockshut, Dr W. E. Dobnan, Dr Mary Esslemont, Dr F. Gray, Dr E. A. Gregg, Lord Horder, Dr J. A. L. Vaughan Jones, Dr W. Jope, Dr J. F. Lambie, Dr J. B. Miller, Dr H. Seaward Morley, Dr J. A. Pridham, Dr S. Wand, Dr S. A. Winstanley.

The Insurance Acts Committee has received from the General Practice Subcommittee a report of its activities since it was appointed, and this is now passed on for the information of Local Medical Committees (see Appendix).

**Remuneration of General Medical Practitioners**—A special subcommittee has been formed to prepare a case for an improvement in the remuneration of general medical practitioners in the National Health Service.

**Mileage**—It is being recommended to the Central Mileage Distribution Committee that with a view to implementing the Spens Report in its reference to the position of rural practitioners, medical practices should be graded so that the ordinary portion of the Mileage Fund can be distributed on a basis which will give the doctor in a sparsely populated area a higher unit value than those in more populous districts.

**Certification**—The Committee has been concerned jointly with the General Practice Committee of the B.M.A. in the preparation of the Association's memorandum of evidence to the Departmental Committee which the Minister of Health appointed to advise on how far it would be practicable to improve and simplify as well as reduce the number of forms of certificate then in use. The memorandum was published in the *B.M.J. Supplement* of May 29 1948.

**Medical Card**—The Insurance Acts Committee made a number of proposals for the amendment of the medical card. These proposals could not be made in time for consideration by the Ministry before it was necessary to proceed with the printing of the medical card but they have been noted for discussion with the profession's representatives before the card is reprinted.

**Change of Doctor**—The Committee expressed the view that without prejudice to the proposal that an insured person should be allowed to change his doctor at any time under the National Health Service it should be a requirement that application be made to the Local Executive Council on each such occasion. The Ministry of Health did not agree with the Committee's pro-

posal, mainly on the ground that patients should enjoy the same freedom to change their doctor as private patients enjoyed.

**Pharmaceutical Services in Rural Areas**—Discussions have taken place between the Rural Practitioners Subcommittee and representatives of the chemists in regard to the provision of pharmaceutical services in rural areas. The chemists desired that the one mile limit which, under the N.H.I. Act determined whether a patient should receive his medicine from his doctor or a chemist should be increased to two miles, and that the regulations should provide that the insured person's right of choice should operate only where there was a pharmacy within a reasonable distance of the doctor's surgery. The Rural Practitioners Subcommittee came to the conclusion that the extension of the limit of distance suggested by the chemists was impracticable. Doctors in many rural areas were quite prepared to give up dispensing but they felt it was their duty to ensure that a complete twenty-four-hour service could be made available by the chemist regardless of the distance from the chemist's premises. The rural practitioner could not accept a position under which he was asked to undertake the dispensing for a minority of the patients, which would be uneconomical. The problem was not capable of being dealt with on a national basis and would have to be considered in each area in the light of the prevailing circumstances. The Subcommittee favoured the formation of local liaison committees of doctors and pharmacists for the consideration of dispensing in rural areas.

**Chemists' Hours**—The Ministry's instructions to Local Executive Councils concerning the provision of pharmaceutical services included a model scheme providing, *inter alia*, that one or more places of business in each area shall be open at all reasonable times. The model scheme suggests that a rota be established whereby one or more places of business in each district shall be open for one hour in the evening on early closing days, for one hour on Sundays and public holidays, and for one hour in the evening after 6 p.m. on other days.

**Meetings of Local Executive Councils: Payment for Loss of Remunerative Time**—Regulations made under Section 54 (5) of the National Health Service Act provide for payment for loss of remunerative time to, *inter alia*, members of Executive Councils. The maximum sum allowed under the regulations is '20s for one day or 24 hours'. The Committee's view is that it should be left to each individual medical member of a Local Executive Council to make his own decision regarding the application for payment for loss of remunerative time in attending meetings of the Council or its committees.

On the question of subsistence allowance the Committee feels that the minimum period for which it should be payable should be reduced from five to four hours.

**Statutory Levy for Expenses of Local Medical Committees**—The attention of the Ministry was drawn to the absence from the National Health Service Act of provision for a statutory levy method of collecting funds for the expenses of Local Medical Committees. The omission will be rectified in the Amending Bill which the Minister of Health has promised to present to Parliament in the near future. In the meantime Local Executive Councils have been instructed to advance funds to Local Medical Committees on request, the understanding being that any such advance payments will be recovered by deductions from the remuneration of the general practitioners concerned when statutory authority has been given for such deductions.

**General Practitioners and Special Departments of Hospitals**—The Ministry of Health is to be asked to give general practitioners the privileges they enjoyed before the National Health Service in being able to obtain x-ray and pathological examinations by direct application to hospitals.

#### National Insurance (Maternity Benefit) Regulations, 1948

A National Insurance Advisory Committee has been established to consider and report on the representations of any bodies or persons interested in draft regulations prepared under the National Insurance Act 1946. Draft regulations for the administration of maternity benefit came before this Committee and the Association was asked whether it wished to make any observations on them. The Insurance Acts Committee considered the regulations and came to the conclusion that they included one or two provisions which seemed to be objectionable.

## eight minutes to go . . .

Doctors today find that a large number of their patients complain of constant tiredness, of 'finding everything too much', of feeling generally run down. Cases of debility and lassitude caused by present-day conditions are becoming increasingly prevalent. For these conditions 'Vibelan' is of particular value. It counteracts B vitamin deficiencies, containing as it does the principal members of the B group in the balanced proportions which are necessary for effective utilisation of proteins, fats and,

more especially, carbohydrates. Each tablet contains vitamin B<sub>1</sub> 0.5 mg, riboflavin 0.75 mg and nicotinamide 7.5 mg, in a yeast extract base. Four tablets provide the normal daily requirement of these vitamins. 'Vibelan' is available in bottles of 50 tablets. Further details are available on request.

**VISCOPASTE AND ICTHOPASTE BANDAGES**

Viscopaste and Ichthopaste bandages are recommended as an alternative to elastic adhesive bandaging in the treatment of chronic varicose and eczematous conditions and where the patient's skin is hyper-sensitive.

Both bandages have non-fray edges and are thoroughly impregnated with zinc oxide gelatin paste of the Unna type. Ichthopaste contains in addition 2% Ichthyol.

Available in 6 to 10 yd lengths by 3½ in wide.

Descriptive literature may be obtained on request to the Medical Department of the Manufacturers.

REDUCING HEAT RASH AND SKIN IRRITATIONS

## Johnson's BABY LOTION

used after nappie changes  
Johnson's Baby Lotion  
spreads a discontinuous  
film that allows the  
skin to "breathe"  
naturally

One of the chief causes of chafing and infant skin irritations is perspiration that cannot escape freely. Johnson's pure white antiseptic Baby Lotion leaves a soothing discontinuous film on the skin that protects it against surface bacteria and at the same time allows it to breathe easily because the oil in water emulsion is homogenized under pressure to provide extreme dispersion of the oil in micron-size globules. Thus perspira-

tion can readily escape and the chances of heat rash and irritations are reduced. Laboratory and clinical tests show that used after nappie changes Johnson's Baby Lotion is the perfect product for baby skin care—and a very important step forward.

EVANS

In Clause 3 (2) the Ministry of National Insurance was given the power to require a woman to submit to a medical examination in any case in which the correctness of a certificate given by a qualified practitioner (defined in the Act as "a registered medical practitioner, or certified midwife, or such other midwife as may be prescribed") was in question.

Under Clause 4 (2) (c) a woman could be disqualified for receiving a maternity allowance if she failed without good cause to attend for such an examination. The Insurance Acts Committee contended that no steps should be taken to require a woman to submit to a medical examination by a second practitioner without reference to the woman's doctor.

Clause 4 (1) (b) disqualified a woman for receiving an attendance allowance if she failed without good cause to follow the advice of a duly qualified practitioner in her case and to answer any reasonable inquiries by the Minister or his officers as to the advice given to her by a qualified practitioner. It was felt that no authority should be given to a lay person to discuss with the patient or comment on advice given by the doctor, which might well include diagnosis.

The Advisory Committee dealt sympathetically with the Insurance Acts Committee's representations, and the regulations in their final form are unobjectionable.

#### Postgraduate Courses for General Practitioners

Several motions on the subject of postgraduate courses for general practitioners, referred to the Insurance Acts Committee by the 1947 Annual Conference, have been carefully considered and the following views expressed.

Wherever possible, and where all the conditions are suitable, general practitioners should be given facilities for attending their patients in hospitals.

Whilst the short course of postgraduate study has its advantages, the Committee is of opinion that a more extensive course of not less than one month is preferable.

Where it is necessary for a medical practitioner to engage a locum (in the normal sense of the term) his claim for a fee towards the cost of engaging a locum, up to the prescribed maximum, should be allowed without question.

#### Part-time Regional Medical Officers

Representations to the Ministry of Health resulted in an increase in the sessional fee for part-time Regional Medical Officers from 2' to 3 guineas for a session of two hours with effect from Oct 1, 1947.

#### Doctors and the Petrol Shortage

The 1947 Annual Conference voted in favour of doctors being given freedom to use their cars at all reasonable times provided they were "on call." This was agreed to by the Minister of Fuel and Power.

#### Doctors' Cars

The 1947 Annual Conference asked that priority be given to doctors by the manufacturers of cars, and not through the usual agency channels. Although it was not possible to achieve this in all cases it was hoped that concerted action by all the interested parties, including Government Departments, would result in an improvement of the situation. Unfortunately, there have been further cuts in the number of cars available for the home market, but every effort is being made to secure early delivery in cases of real need.

#### Pension and Insurance Scheme for Insured Practitioners

The companies concerned in the Pension and Insurance Scheme for Insurance Practitioners have given notice that no new proposals will be accepted after Dec 4 1948. It is hoped that it will be possible to arrange for a new scheme to replace the one which will shortly cease to operate.

#### National Insurance Defence Trust

The balance-sheet and statement of expenditure and income for the Trust for the year ending Dec 31, 1947, are being sent to every Local Medical Committee.

The Special Conference of Representatives of Local Medical and Panel Committees in March last endorsed the action of the trustees in voting the sum of £400 000 as an initial contribution from the Trust to the Independence Fund, which was

established in the early part of this year to finance the profession's activities during the dispute with the Government over the National Health Service. When the Independence Fund was wound up it was agreed that the Trust and the Central Contingency Fund of the B.M.A. should share the administrative expenses of the Fund, thus enabling all individual subscribers to have their contributions returned to them without deduction.

The trustees have already expressed themselves strongly in favour of continuing the Trust for the purpose for which it was founded in 1919, and they are now considering to what extent it is desirable that efforts should be made to enlarge the Fund to meet all possible contingencies.

#### SCOTLAND

This particular section deals with matters which are of a purely domestic Scottish nature and which have not been referred to in the preceding paragraphs, or upon which action in England and Wales differs from that taken in Scotland.

#### Chairman and Deputy Chairman

Dr A. F. Wilkie Millar and Dr W. M. Knox were appointed chairman and deputy chairman of the Scottish Subcommittee respectively for session 1947-8.

#### Advisory Distribution Committee of the Department of Health

The following were reappointed as nominees of the Scottish Subcommittee on the Advisory Distribution Committee: Dr A. F. Wilkie Millar, Edinburgh, Dr John Lambie, Glasgow, Dr G. W. Ireland, Pathhead, and the Scottish Secretary.

#### Medical Advisory Committee

The Department of Health was informed that all members of the Scottish Subcommittee would be available for service on Medical Advisory Committees constituted under the Medical Benefit Regulations (Scotland), 1938.

#### National Health Service

The deliberations of the Subcommittee during the past year have been concerned mainly with matters arising from the National Health Service. The Subcommittee has had before it a number of forms to be issued under the regulations of the Scottish Act and has made suggestions for their modification to the Department of Health.

The Department has been informed that the Subcommittee would raise no objection to the introduction in Scotland of a new form for notification for treatment of temporary residents similar to that proposed for England and Wales.

The Subcommittee has had an opportunity of scrutinizing, in its relation to Scotland, the statement of evidence prepared by the Association for submission to the Departmental Committee on Medical Certificates, and has not considered it necessary to make any suggestion for amendment or addition so far as Scotland is concerned. A recommendation has however, been made to, and accepted by, the Scottish Committee that a small *ad hoc* committee should be appointed for the purpose of giving evidence before the Departmental Committee in respect of those certificates which under Scottish law differ from those required under English law—e.g., Soul and Conscience, and Death Certificates. It has also considered, in conjunction with the General Practice Subcommittee of the Scottish Negotiating Committee, the list of enactments under or for the purpose of which practitioners in Scotland may be asked by their patients to issue medical certificates, and has drawn the attention of the Department to certain directions in which it considers the list requires amendment.

#### Fees for Emergency Treatment and Anaesthetics

The Department of Health has been informed that so far as Scotland is concerned it is not desired that the English example of charging fees for emergency treatment and anaesthetics against the National Pool should be followed and that the question of a deduction for this purpose from the area pool should be left to local determination.

#### Medical Members of Scottish Health Services Council

The Subcommittee has joined with the Scottish Committee of the Association in nominating to the Secretary of State the

names of medical practitioners for his consideration in appointing the 18 medical members of the Scottish Health Services Council

#### Conference of Representatives in Scotland

A useful Conference was held at the Scottish House of the Association on March 10 1948. The Conference was composed of representatives of Divisions in the Representative Body, representatives to the Conference of Local Medical and Panel Committees, members of the Scottish Committee, and members of the Insurance Acts Scottish Subcommittee. The object of the Conference was to give the profession in Scotland an opportunity for general discussion of the National Health Service Act (Scotland) before the Conference of Local Medical and Panel Committees on March 16 and the Special Representative Meeting of the Association on March 17.

### APPENDIX

## NATIONAL HEALTH SERVICE

### REPORT OF MATTERS DEALT WITH BY THE GENERAL PRACTICE SUBCOMMITTEE OF THE NEGOTIATING COMMITTEE

#### (1) Partnership Agreements in Relation to Compensation

A memorandum of evidence has been prepared and submitted to the Legal Committee on Partnerships appointed by the Minister of Health. Witnesses have appeared before the Committee in support of the memorandum, and it is understood that the Committee will report to the Minister very shortly.

The following proposals formed the basis of the memorandum submitted on behalf of the profession:

(a) That where all or both the partners join the Service on or before the appointed day existing partnership agreements should remain operative after July 5, except for the passage of money in respect of goodwill under purchase options and obligations.

(b) That compensation should be based upon the share held by each partner on the appointed day.

(c) That when a partner in the Service is required to take over a share from a partner who is not in the Service, the vendor should be paid forthwith for the share from public funds other than the global sum in accordance with the undertaking given by the Minister of Health to make such payments possible. It would be possible by a mutually agreed modification of the existing agreement for the vendor to sell his share to a third practitioner outside the Service.

(d) That in the case of a practitioner who remains outside the Service and is under an obligation to purchase a share of the practice from a partner who joins the Service purchase options and obligations in the existing partnership agreement should be cancelled.

(e) That if the Legal Committee on Partnerships does not report till after the appointed day, it should be possible for a practitioner in partnership who, because of doubt as to his position has not then joined the Service, to do so after July 5, if he so wishes after considering his position in relation to the Amending Act and that compensation should be payable with retrospective effect from July 5.

#### (2) Medical Practices Committee

An invitation was received from the Minister of Health for nominations for the Chairman and six members of the Medical Practices Committee. The following were nominated and have been appointed: Dr W E Dornan (Sheffield) (Chairman), Dr P V Anderson (Shildon Co Durham), Dr D B Evans (Wrexham), Dr Annis Gillie (London), Dr D T McDonald (Belford Northumberland), Dr J F Murphy (London), Dr J A Pridham (Weymouth).

#### (3) Remuneration of General Medical Practitioners— Distribution of Practitioners' Funds

The Ministry's original intention was to base the remuneration of general medical practitioners for the first quarter on the number of persons on their lists at July 5. The Subcommittee felt that July 5 would be disadvantageous to a number of medical practitioners particularly those who had not previously been engaged in public medical practice and urged that a much later date be fixed. It was therefore suggested that the basis of calculation for the first quarter should be the numbers on doctors' lists at the middle of September but the Ministry pointed out that this would give rise to difficulties in many Local Executive Council offices owing to the volume of work

involved in dealing with applications for inclusion in doctors' lists. Eventually it was agreed that the distribution of the Central Practitioners' Fund between areas should be based upon the total number of persons on doctors' lists on July 31, and that Local Executive Councils would be urged to distribute the Practitioners' Fund in proportion to the number of patients actually on doctors' lists at the latest date in the period on which the Council could make the necessary count. The Subcommittee urged that this should not be earlier than the middle of August.

The Ministry has appointed two Distribution Committees: (1) An International Distribution Committee to determine the apportionment of the Central Practitioners' Fund between England and Wales and Scotland, and (2) a Distribution Committee for England and Wales. The Subcommittee's nominees for these two Committees were accepted by the Ministry, and are as follows:

*International Distribution Committee*—Dr E A Gregg (London), Dr Wm Knox (Glasgow), Dr J D Wells (Billericay, Essex), and Dr E J Rees (Pontypridd).

*Distribution Committee*—Dr E A Gregg (London), Dr D J B Wilson (High Wycombe), Dr E J Rees (Pontypridd), and the Secretary of the General Medical Services Committee of the BMA together with Dr J C Pearce (Diss, Norfolk), Dr J D Wells (Billericay, Essex), and Dr C F R Killick (Williton, Somerset) when questions concerning mileage are under consideration.

The payments to individual doctors for the first quarter ending Sept 30 have given rise to some dissatisfaction. Although these payments are no more than 'payments on account' it is apparent that many of the discrepancies of payment between area and area and practitioner and practitioner were due to the inability on the part of the Executive Councils to check the completed forms EC 1 received in time for the first quarterly payment. An assurance has been obtained from the Minister that every effort will be made to speed up the checking of EC 1s to enable future payments to be made on reasonably accurate lists.

#### (4) The Fixed Annual Payment (Basic Salary)

The Subcommittee had an opportunity of discussing with the Ministry of Health a draft of the statement issued to Local Executive Councils on the conditions under which the fixed annual amount of £300 would be paid. The statement in its final form is as follows:

The new regulations also indicate the conditions of payment of the fixed annual amount of £300. The payment will be made only to those doctors who elect to have it and who receive the consent of the Executive Council (after consultation with the Local Medical Committee) or, on appeal, of the Minister. (When the fixed annual payment is made the capitation fees will be adjusted as indicated in paragraph 3 (b) of the Memorandum on the Remuneration of General Practitioners.) The Minister considers that consent ought to be given in cases where there is reasonable justification for so doing. Such justification might exist in the case of a doctor who is starting a new practice or working up a small one, the doctor who on account of age or ill health is unable to do as much as he has done in the past (when it is necessary that his services should be given), or the rural doctor in a sparsely populated area who cannot attract a large list (though these last cases will normally be covered by an inducement payment). It is possible that in a few areas where the proportion of doctors to the population is at present unusually high the coming into operation of the National Health Service may result in a drop in doctors' incomes. Consent should therefore also be given in the Minister's view in any case where a doctor's income can be shown to have dropped substantially as a result of the new service involving an element of hardship.

The Council are asked in circulating the new regulations, to inquire of doctors whether they desire payment of the fixed annual amount and if so, from what date. (This inquiry should not, for the time being, be made of doctors who are exempted from the liability to have persons assigned to them. A subsequent Circular Letter will deal with the remuneration of such doctors.) Where an application is received and consent refused, the applicant should be informed of his right to appeal.

Further information about the financial arrangements will be circulated later.

The Ministry agreed to a modification of the amending regulation dealing with the fixed annual payment so as to give Local Executive Councils the right to question from time to time the continuance of the payment in individual cases.

### 5) Remuneration of General Practitioners for Services Rendered in Hospitals, Convalescent Homes, Etc

In the Interim Terms of Service under Regional Hospital Boards there is a section dealing with the employment of general medical practitioners. It is stated that the general practitioner may provide general medical care as a member of the staff of a hospital in the following capacities (a) as one of the staff of a general practitioner ("cottage") hospital, and (b) as a part-time medical officer of a convalescent home or other institution, and that for both these groups it will be necessary to enter into a contract with effect from the appointed day.

This section points out that a doctor's capitation fee covers general practitioner services given to a patient on a doctor's list, or on that of his partner, whether or not the services are rendered in hospital. In order to provide remuneration for hospital work for other patients, however, a staff fund is to be created by making a payment of £25 per annum for each bed (other than private pay-beds) occupied on the average in the hospital, the fund to be shared between the general-practitioner staff as they may themselves determine. This payment of £25 per annum for each bed is regarded as insufficient, and representations are being made accordingly.

In regard to the second group—namely, part-time medical officers of convalescent homes, etc—the average time given to this work will be assessed and aggregated in terms of half-days per week, and a contract offered accordingly. The provisional rates of remuneration are to be £100 per annum (non-resident) for each half day per week up to a maximum of £800 for eight or more half-days, and subject to review when the remuneration of specialists has been determined. A protest is being lodged against what appears to be an assumption that the remuneration of the general practitioner should be approximately one half of that paid to specialists. (In the provisional terms of service consultants and specialists in contract with Boards of Governors and Regional Hospital Boards on a part-time basis are receiving £200 per annum for one half-day per week.)

In so far as these contracts relate purely to non-specialist services, the Subcommittee has made no comment. It has sought an assurance, however, that the permanent arrangements will be based upon a more accurate assessment of the amount of the staff fund created for each hospital. The method of assessment in the case of medical officers of convalescent homes was criticized and the hope was expressed that it would not be applied too rigidly. An assurance has been given that, although there must be an assessment and means of correction, the Ministry is anxious that the assessment shall not be applied with hardship to the doctors concerned. The Ministry has agreed that in assessing a medical officer's remuneration it is reasonable to take time spent in travelling into account.

### (6) Special Inducements Fund

A sum equal to 1% (approximately £400,000) of the Central Practitioners' Fund (but not part of that Fund) has been established to provide inducement payments to assist doctors to practise in peculiarly difficult areas.

The Subcommittee has discussed with the Ministry the grounds upon which applications for grants from the Fund might be based. These are as follows: (a) Vacancy advertised but no applications received. (b) Vacancy to be advertised for an area which has in the past always attracted too few doctors. (c) An existing doctor unable to remain for the income which he might expect to receive from providing general medical services without an inducement payment. (d) An existing doctor who previously received special assistance under the National Health Insurance Scheme, which will no longer continue and the loss of which will cause undue hardship. (e) An existing doctor with an abnormal number of aged and chronic sick on the list, or a vacancy in an area with an abnormal number of such persons resident there.

In the original direction to Local Executive Councils it was indicated that inducement payments should not be made in cases where the difficulty can be met by an annual fixed pay-

ment (basic salary) of £300. The Ministry was reminded that this was not in accordance with the underlying principles of the Special Inducements Fund, and has been asked to further advise Local Executive Councils that it is not intended that a payment from the Special Inducements Fund should depend upon the receipt of a fixed annual payment. On the other hand, when a fixed annual payment is appropriate—e.g., where a doctor is building up a new practice—it would be payable instead of an inducement payment.

Executive Councils have been asked to inform the Ministry of any cases where they are satisfied, after consultation with the Local Medical Committee, that general medical services adequate to the needs of the district cannot reasonably be expected to be maintained without an inducement payment. In such cases Executive Councils have also been asked to indicate the sum which they consider is required by way of an inducement payment. The Ministry will then refer the Executive Councils' proposals to the Medical Practices Committee for advice on the payments to be made in individual cases within the total sum available for distribution. The Ministry's decision will subsequently be notified to the Executive Council.

All payments approved by the Ministry are to be reviewed annually by the Local Executive Council concerned, and a report as to the need for continuance made to the Ministry, after consultation with the Local Medical Committee.

The Subcommittee has emphasized the desirability of speedy consideration of applications and the importance of making allocations to practitioners from this fund as soon as possible.

### (7) Fees for Specialist Services Rendered by General Practitioners

The Ministry's attention has been drawn to Clause 10 of Part I of the First Schedule to the General Medical and Pharmaceutical Regulations, which makes it unlawful for a general practitioner to demand or accept a fee for any medical treatment, regardless of whether it is a general practitioner service or not, given to his patients or patients of his partner or assistant.

The Subcommittee submitted that it was inequitable to deny a practitioner who possessed the necessary skill and experience the right to render services of a specialist character and receive the appropriate fee if his patients wished him to render such services. The alternative would be to refer the patient to a medical practitioner under contract with the Regional Hospital Board/Board of Governors, a course which might not be acceptable to the patient, and which would inevitably be an unnecessary strain on the hospital services.

One effect of the prohibition in Clause 10 would undoubtedly be to discourage general medical practitioners from raising the standard of their medical knowledge, with consequent disadvantage to the public and the Service. It was pointed out to the Ministry's representatives that a number of services, such as operations for tonsils and adenoids, circumcisions, and injections for haemorrhoids and varicose veins, were frequently given by general practitioners possessing the necessary skill and experience which would otherwise have to take their turn on a long waiting-list at the local hospital, that the present prohibition would be a hardship in country districts where specialist services were often rendered by general practitioners, that in many cases the practitioners concerned possessed a certain degree of professional skill but did not acquire the status necessary to secure an appointment under the Regional Hospital Board, and that the Local Medical Committee had in the past and could in the future effectively check all claims to charge fees for specialist services.

### (8) Fees for Anaesthetics for Dental Operations

A definite assurance has been given that the administration of an anaesthetic for a dental operation is outside the range of treatment which a practitioner is required to give to his patients under the General Medical and Pharmaceutical Regulations, and that he is entitled to receive an appropriate fee. It remains for this fee to be negotiated with the Ministry.

### (9) Grants for Training Assistants

The Ministry of Health put forward the following suggestions in connexion with the proposed grants to general practitioners for training assistants

1 *Amount of Grant*—£150 plus assistant's salary and boarding expenses (not exceeding £700) Car allowances, if additional car used (not exceeding £150)

2 *Practitioners Eligible for Grant*—General practitioners approved by the local medical committee in consultation with two persons nominated by the University for the area of the Regional Hospital Board. All general practitioners will be given an opportunity to apply

3 *Assistants Qualifying for Grant*—Medical practitioners who have not previously been in general practice in the British Isles otherwise than for short periods as a locum

4 *Conditions Attaching to Grant*—(a) The period of training covered by the grant is one year. (b) Grant may not be paid for more than one year's training for each assistant. (c) A practitioner is not entitled to grant in respect of more than one assistant during the same period. He may, however, employ an assistant in the ordinary way at the same time as an assistant for whom a training grant is being paid. (d) To qualify for a grant a practitioner must have not less than 2,000 patients on his list. He will not be entitled to increase his list of patients beyond the usual maximum in respect of an assistant for whom grant is being paid

The Ministry explained that the doctor training the assistant would be responsible for the employer's share of (a) the national insurance contributions paid in respect of the assistant, and (b) the superannuation contributions payable in respect of the assistant under the National Health Service Superannuation Scheme

It was intended that the payment not exceeding £700 to be made to the principal in respect of the expense of employing an assistant should also cover this item. The grant of £150 would be paid in addition

The Ministry's explanation that the employers' share of contributions payable in respect of the assistant's national insurance and superannuation would come out of the £700 has been strongly criticized. The effect would be to reduce the maximum of £700 to £640 less the assistant's own share of national health and superannuation contributions. It has been pointed out that the doctor training the assistant will not be permitted to increase his list beyond the usual maximum that the £700 he receives will be passed on to the assistant, possibly with an addition by himself, that figures had been published without any hint that they must be subject to these deductions, and that a trainee should be regarded as a student rather than an employee

The Ministry in reply to further representations, states

We agreed to pay £150 grant to principal, £700 towards cost of assistant, plus up to £150 for a second car where necessary. The £700 was intended to cover the additional expense incurred in respect of the assistant and necessarily included the employer's superannuation contributions

An experienced assistant gets £700-£800 (vide current *British Medical Journal* advertisements). A trainee assistant should get less. If the salary were £650 the cost to the principal would be £650 plus 8% plus £11 (N.I.), or £713. At £640 the cost would be £702, but the £63 or £62, as the case may be, would be practice expenses and rank for income tax allowance

An assistant getting £650 would have to pay £51 in superannuation and national insurance contributions, leaving roughly £600. In his case too the contributions would be allowed in assessing income tax

The car allowance of £150 (maximum) is, we think, generous. Current *B.M.J.* advertisements give £100

### (10) Mileage

It has been agreed that the sum of £1,300,000 shall be set aside for mileage payments to general medical practitioners in rural and semi-rural areas. This figure is subject to review in the light of experience. It has been suggested that mileage payments should consist of two elements: (a) ordinary mileage and (b) reserve (special difficulties) mileage, the Central Mileage Fund being divided between these two elements in the same ratio as the former Central Mileage Fund was divided. These two elements will not cover payments for special expenses such as were previously paid from a portion of the Central Mileage Fund known as the 'Special Expenses Portion,' nor will they cover the Highlands and Islands Medical Service

It was suggested that these would be charges on the Special Inducements Fund of £400,000 which the Minister had already agreed to provide in addition to the funds for treatment and mileage

Consideration is to be given to the possibility of establishing a single United Kingdom Mileage Fund with an agreed universal unit as the basis of distribution

### (11) Dispensing Capitation Fee

After consultation with the members of the Rural Practitioners Subcommittee the Ministers' offer of a dispensing capitation fee of 6s 6d per annum for doctors in England and Wales has been accepted without prejudice to revision as a result of negotiations at a later date. Before the fee is reviewed there is to be an investigation into dispensing costs

### (12) Maternity Medical Service

Following the decision of the Minister that a doctor not on the Obstetric List could make arrangements with a patient on his own list for the provision of maternity medical services for which a fee of 5 guineas would be payable by the Local Executive Council, the Ministry submitted proposals for payment when the complete service is not given. Objection was taken to the fragmentation of the 5 guinea fee, mainly on the ground that doctors not on the Obstetric List are not statutorily required to undertake the full services expected of their colleagues on the Obstetric List, and that the reduced fee of 5 guineas was accepted because the range of medical care which a practitioner will be required to give under the Act to one of his public patients does not necessarily exclude any antenatal care he might consider necessary. The matter is still under discussion. Application is being made for payment for mileage, in appropriate cases, in connexion with maternity medical services

The Subcommittee drew attention to the absence of provision for the administration of an anaesthetic in the arrangements for maternity medical services under the Act, and the Ministry has since announced that a fee of £1 15s will be paid for the services of an anaesthetist with, in addition, mileage at the usual rate for the district (with a limit of one mileage fee for one journey)

The Subcommittee ascertained that the position in relation to maternity cases booked before the appointed day but actually attended in confinement on or after July 5 was that the relevant portion of the agreed fee (7 guineas or 5 guineas, as the case may be) will be paid out of public funds, and the medical practitioner will be entitled to recover from the patient fees for services rendered before the appointed day in connexion with the pregnancy

Where the patient is admitted to a hospital during labour having already been attended in labour by her doctor, the doctor is entitled to receive the full fee for the service rendered

### (13) Local Obstetric Lists

It is understood that a doctor whose name is included in the Obstetric List for an area may undertake maternity services (on the 7-guinea scale) in any other area

Exception was taken to the publication in post offices and other places of the names of doctors on the local Obstetric List. It was suggested that it would be sufficient for the names of these doctors to be made available to the general practitioners and midwives in the area. The Ministry has not accepted this recommendation but has suggested to Executive Councils, as an alternative, that they can indicate the doctors providing maternity medical services by some suitable symbol on the general part of the list

### (14) Provision of Medicines and Appliances for Private Patients

The Subcommittee has pressed for the provision through the National Health Service of necessary medicines and prescribed appliances for persons who are being treated as private patients. It was submitted that, subject to reasonable safeguards against abuse, patients receiving medical attendance as a matter of private arrangement should be entitled to receive medicines and prescribed appliances through the National Health Service. It was recognized that there would have to be safeguards against abuse but it was pointed out that payment for

general practitioner services was being withheld in respect of 5% of the population on the assumption that they would prefer to be treated as private patients. It would not be unreasonable, therefore, to ask that the cost of their medicines should be paid from public funds.

It is the Minister's view that prescribing and dispensing are essential parts of the treatment and cannot be dealt with as though one of them were something separate. The Ministry has considered the possibility of making available, through the hospital service to patients treated privately, particularly expensive and life saving medicines (insulin and liver preparations, etc.) where the cost would represent a hardship for the individual, but does not think that any workable arrangement on these lines is possible. In spite of further representations the Ministry has not found it possible to change its views.

#### (15) Treatment of Members of Staffs of Hospitals and Similar Institutions, and Students at Universities and Public Schools

The Subcommittee drew attention to the absence of freedom of choice of doctor for persons employed and resident in hospitals and similar institutions, where such persons are required to join the list of a member of the medical staff. It is understood that a similar situation has arisen in certain universities and public schools, where the students are being required to join the lists of the university or school doctor, becoming temporary residents during vacation. In effect, the parents of these students have no freedom of choice of doctor. It is regarded as important that, normally, the family doctor should keep the record of the patient, and the parents should be able to exercise their right of selecting either the school doctor or the home doctor as the child's normal medical attendant.

The Ministry undertook that on all possible occasions it would be made clear that there is complete freedom of choice of doctor.

#### (16) Model Allocation Scheme

The attention of the Ministry was drawn to paragraph 2 of the Model Allocation Scheme, which requires the practitioner who refuses to accept a person on his list to give the applicant such treatment, if any, as might be required by him pending his acceptance or assignment to a practitioner, but it does not place any limit of time on the period during which the practitioner is responsible for treatment in these circumstances. The Subcommittee suggests that the paragraph should specify a time limit of not more than 14 days.

It is understood that in many of the draft schemes submitted to the Ministry, a time limit of seven to 14 days has been inserted. An assurance has been given that an addition of this nature will not be questioned in other schemes, and the desirability of making it universal will be borne in mind when the model scheme is revised.

(Paragraph 5 (1) of the Model Allocation Scheme requires any practitioner who is summoned to an accident or other sudden emergency, to give any necessary treatment. In the corresponding paragraph of the Allocation Scheme, under the old NHI Medical Service the words "and is available" appear before the word 'summoned' and the Subcommittee asked that these words be inserted in the New Model Scheme.)

The Ministry's lawyers say that the missing words are unnecessary, but an assurance has been given that their inclusion will be borne in mind when the scheme is revised.

#### (17) Change of Doctor

Regulation 14 entitles a person already on a doctor's list to make application at any time to another doctor for acceptance on his list. It was suggested to the Ministry that it was desirable that a person should give notice to the Local Executive Council of his desire to change his doctor, and that the only exception to this requirement should be in cases where the change was arranged with the consent of both doctors concerned.

In declining to adopt the Subcommittee's suggestion the Ministry made a comparison with the position of the private patient who is able to change his doctor whenever he pleases.

#### (18) Sale of Practice of Medical Practitioner on Obstetric List Only

The Ministry is advised that the Act prohibits the sale of the goodwill of a practice where the name of the owner is

included only on the Local Obstetric List maintained by an Executive Council. At the Subcommittee's request prominence was given to the ruling well in advance of the appointed day.

#### (19) Certification

The Subcommittee has considered the list of enactments under or for the purpose of which doctors may be asked by their patients, or the legal representatives of patients who have died, to issue medical certificates free of charge. The list is confined to occasions when certificates may be required and does not include any form of medical report.

A protest has been lodged against the action of the Ministry in issuing the list without first consulting the profession's representatives, and it has been made clear that the list must be regarded as provisional until the Departmental Committee on Certification has reported and there have been discussions with the Ministry on its recommendations. In the meantime three points have been raised.

1 Serial 2 includes a requirement to provide a certificate to support an application for guaranteed weekly remuneration or statutory holiday. These are felt to be purposes for which certificates might be provided by persons other than medical practitioners, and the Ministry has agreed to pass the Subcommittee's comment on to the Departmental Committee.

2 In connexion with Serial 15, the Subcommittee submitted that the only purpose for which a parent requires a medical certificate under the Education Act is when the parent is summoned for the non attendance of a child at school. This is not clearly understood by medical practitioners generally, and the Ministry has accepted this position, with an undertaking to deal with the matter in an early circular to Education Councils.

3 The Subcommittee suggested that whole time medical officers of hospitals and similar institutions should be authorized and requested to issue certificates on the official forms in cases where patients attending the hospital are not under treatment by their own doctors. This has been done.

The attention of the Ministry of National Insurance has been drawn to the wording of the Maternity Certificate, which requires a medical practitioner to specify the day of the week on which the confinement is expected to take place and the words 'on the week commencing' both of which give rise to difficulties.

The Ministry of Health and the Ministry of National Insurance are jointly concerned in the machinery for the investigation of cases of alleged contravention of the certification rules, and the suggestion was made that, in cases where the doctor is a "first offender" or the breach of the rules is not of a serious nature, an informal visit might be made to the doctor concerned by the Regional Medical Officer, who would do little more than bring the matter to the notice of the doctor and discuss any difficulties. In every case of this description no disciplinary action would result from the visit to the doctor. The Subcommittee took no exception to the suggestion on the understanding that the RMO would be unaccompanied on his first visit to the doctor.

#### (20) Postage on Official Communications

Inquiry was made of the Ministry as to the arrangements for refunding to doctors the cost of postage on official communications connected with the National Health Service. The Ministry was reminded that under the National Health Insurance Act the aggregate of postage paid by doctors in each insurance area was passed on to the Panel Committee, and in that way could be used to reduce the levy on the local doctors for Panel Committee expenses. The Ministry was also reminded that franked envelopes or labels were supplied by many Government Departments—e.g., for income tax communications and correspondence with Regional Medical Officers. The absence of similar facilities when doctors were obliged by their terms of service to send communications to Local Executive Councils was a source of irritation to doctors.

The Ministry's attitude is that a new situation has arisen owing to the enormous increase in the number of communications from private individuals to Government Departments such as Food Offices, etc. Apart from repercussions in other fields, the Ministry doubts whether the amounts involved would justify the volume of work necessary to keep account of them. The Ministry is of opinion that postage is a proper charge on a doctor's practice expenses (which were taken into account in

fixing their remuneration) and does not consider that arrangements for franking envelopes are justified. This view is not accepted and further representations are to be made on the subject.

#### (21) Superannuation—Proportion of Practice Expenses in the Assessment of Contributions

Agreement has been reached with the Ministry of Health on the percentage of income to be deducted for practice expenses in the assessment of National Health Service income for superannuation purposes. The deduction will be 50% of mileage payments and 35% of other payments. The range of "other payments" has not yet been finally determined but it is understood that it will include all fees for maternity medical services and grants (up to £150 per annum) for the training of assistants.

#### (22) Purchase Tax on Medical Record Filing Cabinets

The Ministry's attention was drawn to the fact that medical practitioners are being put to considerable expense in the acquisition of filing cabinets for medical service records. The Subcommittee asked that representations be made to the Chancellor of the Exchequer in favour of the abolition of purchase tax on such cabinets. It was important that the risk of damage to these records should be minimized but it was feared that the present high cost of suitable cabinets might result in improvisation at the expense of the records themselves. Relief from purchase tax would go a long way to avoid this probability. The Ministry was reminded that this was one of the few articles on which purchase tax had been increased in the recent budget.

The Ministry has approached the Board of Customs and Excise, who say they have no authority to remit or refund purchase tax on equipment of this nature, and that there is no possibility of obtaining such authority. Not only are there administrative difficulties in giving preferential treatment to particular classes of purchasers since purchase tax is charged at the wholesale stage but a concession to doctors would make it impossible to resist other claims which could be regarded as equally strong.

#### (23) Medical Treatment of Overseas Visitors

The question of overseas visitors and foreign seamen being allowed to take advantage of the National Health Service without payment during their stay in Great Britain has been raised with the Ministry, and a protest has been lodged against the absence of consultation with the medical profession before a public announcement of the concession was made. The Subcommittee is seeking counsel's opinion on the Ministry's interpretation of the Act in regard to overseas visitors.

#### (24) Expenses of Local Medical Committees

The attention of the Ministry of Health was drawn to the absence of any provision in the National Health Service Act for the expenses of Local Medical Committees. The Ministry has undertaken to include in the proposed Amending Bill provision for a statutory levy if so desired by the Local Medical Committee in any area. In the meantime Local Executive Councils have been instructed to advance funds to Local Medical Committees on their request, the understanding being that any such advance of payments will be recovered by deductions from the remuneration of the general practitioners concerned when statutory authority has been given for such deductions.

So far as voluntary levies are concerned the Ministry has undertaken to give favourable consideration to a request that clerks to Local Executive Councils should be authorized to make appropriate deductions at the request of the Local Medical Committee, upon the understanding that it might be necessary to reserve the right to withdraw the concession if at any time the Minister feels that the purpose for which the deductions are being made are placing him in an embarrassing position.

#### (25) Income Tax Relief in Respect of Diminution of Income

Application was made to the Chancellor of the Exchequer for some relief from tax in cases where owing to the introduction of the National Health Service, a medical practitioner would suffer hardship if required to pay tax on the preceding year's income. It was submitted that this was a situation where the wartime concession, which enabled income to be assessed

on a three-years average, would operate fairly. The Chancellor's reply was that a concession on the lines suggested could not be justified except in the abnormal circumstances of war.

The Minister of Health was asked to support the application to the Chancellor of the Exchequer, but his reply was that he could not agree that many practitioners would lose income owing to introduction of the National Health Service, and that in any event it would be difficult to prove that the loss was due to the Act when it might be due to other causes such as change of popularity, the arrival of new competitors, etc. The Minister's first premise conflicts with a statement in a circular (E.C.L. 34) to Local Executive Councils, "that in a few areas where the proportion of doctors to the population is at present unusually high the coming into operation of the National Health Service may result in a drop in doctors' incomes."

The Minister's reply was discussed with his officers, who thought it was entirely a matter between the doctors and the Inland Revenue. They indicated, however, that if the views of the Ministry were sought by the Commissioners of Inland Revenue the view would be expressed that there were likely to be cases of hardship among doctors in the matter of income tax owing to the introduction of the National Health Service.

#### (26) Medical Card

The Insurance Acts Committee made a number of proposals for the amendment of the medical card. These proposals were not made in time for consideration by the Ministry before it was necessary to proceed with the printing of the medical card but they have been noted for discussion with the profession's representatives before the card is reprinted.

#### (27) Medical Treatment of Services Personnel

An assurance has been given that the total number of persons in the Services is deducted from the total population before arriving at the figure upon which the Central Practitioners Fund is based.

There is to be an early discussion with officers of the Ministry on the position of Services personnel who require medical attention while on leave.

#### (28) Medical Services Committee Procedure

The Ministry's attention has been drawn to Regulation 5 of the Services Committee and Tribunal Regulations permitting (a) a party to an investigation being assisted in the presentation of his case by some other person, and (b) the secretary or other officer of the Local Medical Committee being present when a case is considered by the Medical Services Subcommittee. In the interests of the doctor concerned it is felt to be important that the Secretary of the Local Medical Committee should be acquainted with all the facts of the case, and the Ministry has agreed that copies of all documents issued in connexion with the case might be sent to the secretary of the Local Medical Committee, subject to the agreement of the doctor concerned.

#### (29) Personnel of Tribunal and Tribunal Advisory Committee

The Subcommittee has nominated Dr H Guy Dain as a medical member of the Tribunal to be appointed under Section 42 of the National Health Service Act, with Dr W V Howells (Swansea), Dr J C Pearce (Diss, Norfolk), Dr C F R Killick (Williton, Somerset), and Dr A S Wilson (Gosberton, Lincs) as deputies.

The following have been nominated provisionally for inclusion in the panel of medical practitioners from which the members of Advisory Committees set up under Regulation 11(4) of the Service Committees and Tribunal Regulations will be chosen: Dr P V Anderson (Shildon), Dr J A Brown (Birmingham), Dr H Guy Dain (Birmingham), Dr R O Eades (Ipswich), Dr W Glyn Evans (Wrexham), Dr F Gray (London), Dr E A Gregg (London), Dr J Morgan Rees (Pontypridd), Dr G H Sedgwick (Rotherham), Dr W G Thwaites (Brighton), Dr N E Waterfield (Little Bookham), Dr S A Winstanley (Urmston), Dr W Woolley (Bristol).

#### (30) Fees for Vaccination and Immunization

Discussions are to take place shortly on the fees to be paid to doctors for vaccination and immunization.

## INCORRECT INCOME-TAX DEDUCTION

It has been the established custom over many years for members of the profession engaged in private practice, whether as general practitioners or specialists, to be assessed for the payment of income tax under Schedule D, and this practice has obtained even where the practitioner has held one or more part-time medical appointments. Thus the income from such appointments has been included by the practitioner in the annual return which he has made to the Inspector of Taxes, and he has been able to set against his total professional income the expenses which have been incurred in carrying out his professional work.

The attention of the Association has recently been drawn, however, to cases where a regional hospital board has deducted income tax at source from the remuneration of specialists in part-time contract with the board. This practice is at variance with the normal procedure as outlined above, and not only will it involve specialists in the payment of income tax simultaneously on the income in respect of two separate years but will no doubt lead to difficulty in reclaiming the due allowances on account of professional expenses.

The Association has therefore made a vigorous protest to the Ministry of Health on the subject, and any part-time specialist who has already had income tax deducted at source from his past quarterly remuneration is advised to take the matter up with his regional hospital board without delay.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley

## Correspondence

### Capitation Fee

SIR—Unless action is taken in this matter immediately the N.H.S. is destined to unpopularity by patients and doctors alike and ultimate failure. In the first place, failure is bound to come if doctors' lists are not limited to 2,500 per doctor. This is roughly the proportion of patients to doctors and is definitely as many patients as one doctor can attend to if he is really going to practise medicine and not just become an automatic machine for delivery of prescriptions and certificates and to indicate the way to the nearest out-patient department. Lists of 2,500 would enable the doctor to give good attention to all patients and practise real medicine—the result an efficient and successful service, the 4,000 lists must produce rushed work, scanty treatment, general dissatisfaction among patients, and finally a service unwanted, disreputable, and useless.

Secondly, if doctors are going to give their best they must be adequately recompensed and the proposed capitation fee falls miserably short in this respect. What a farce a scheme for social security—and one of the most important branches of that scheme left with no security at all—vast numbers with badly reduced incomes. There are legion with panels of only 120 or so bringing in income of about £1150 gross—i.e., about £750 net and a pension of £2 or £3 per week if they stay the course until they are 65, and on call 24 hours a day for 7 days a week. Is this social security? This will not do, and the sooner we make it clear to Mr. Aneurin Bevan and Co. the better, even if we have to form a trade union. We were promised a fee in accordance with the Spens Report but were given about 18s., and so any more promises will not do.

I would suggest a graduated capitation fee which would give the smaller panels a fairer deal as the overhead expenses of a small practice are greater in proportion than those of a large

practice, and there will always be small panels in sparsely populated areas and of those just setting out on a medical career. The rate I have in mind would be £2 per head for the first 1,000, 25s for the second 1,000 and 20s for the last 500. With regard to the pension scheme, I would suggest that the years a practitioner has devoted to panel work under the old N.H.I. should be taken into consideration so as to give all a reasonable pension on retirement. We were grossly underpaid under the old scheme, and this would only be giving us a small increase in pay retrospectively.

Finally, I suggest that all practitioners who have ideas similar to those above write to the B.M.A. and also to their Member of Parliament stating their views and requesting immediate action being taken. Where several practitioners are in agreement they might send a conjoint letter—I am, etc.,

Wetherby, Yorks

S. T. PYBUS

SIR—With reference to Dr. Jas. J. Dwyer's letter (*Supplement* Sept 18, p. 127) I gave the answer at the last S.R.M. when I asked the representatives if they were prepared to recommend their constituents to enter the Service without knowledge of terms of remuneration or conditions of service. To accept service under these circumstances, knowing the plenary power vested in the Minister, leaves no option for those who have so committed themselves. Now I cannot understand why the B.M.A. should be decried for lack of attention to the financial side. It should be kept in mind that the Negotiating Body was only empowered to act as such on principles alone—details to be entered into later. Why bleat now?—I am, etc.,

Maidstone, Ken.

S. LAURIE SMITH

SIR—I see that the Government has recently negated its recently proclaimed policy of freezing wages and salaries at least so far as its 'ain folk' are concerned, by recommending an increase on the engineers' claim. Taking cognizance of this fact one is struck by the thought that the time might also be propitious for a claim for a considerable increase in the medical capitation fee, especially taking consideration of the fact that the principle of almost unlimited free certification, without concomitant fee adjustment, which has been so callously hurled upon the already much overtaxed shoulders of this unfortunate profession so unnecessarily, is causing and is likely to cause much greater encroachment on the doctors' time in the future.

I enclose a propaganda leaflet which I have recently received from another medical body, which in my opinion has not been particularly noted in the last few years for its anti-Government attitude, in which one of its immediate objects is stated to be a 30s capitation fee together with numerous boons and blessings. Reckoning on the basis of the *a fortiori* argument one would imagine that the B.M.A. would be fully justified in going in for a 40s capitation fee, bearing in mind the considerable financial loss likely to be sustained by most practitioners in middle and good industrial class areas—in fact, in all but the poorest areas—associated at the same time by a very considerable increase in work at a time when the popular clamour is for more money, more leisure, and less work—I am, etc.,

Manchester

K. V. DEAKIN

### A Salaried Service

SIR—I write to support Dr. R. J. K. Fleming's letter on a salaried service (*Supplement* Sept 11, p. 119). I feel sure that as time goes on more and more doctors will reach the conclusion that the only way to achieve a National Health Service is by the introduction of a salaried service with the doctors working in co-operation instead of competition. We have chased away this bogey of a salaried service to find we retain all the disadvantages and expenses of private practice while losing its advantages.

Does anyone imagine that a health centre could work under the present system of payment? Opportunities for taking on another's patients would be increased, and agreements not to do this while protecting the doctor, would not act in the interest of a patient wishing to change his doctor. Like most compromises the present system lacks courage, vision, and hope for the future. I feel sure that before much longer the idea of a salaried service will gain general acceptance—I am, etc.,

Worsborough Dale, Yorks.

D. W. MAYMAN

## Financial Strain on Young Specialists

SIR—As reported in the *Journal* of Aug 7 (p 318), Sir Ernest Graham Little recently asked a Parliamentary question on the subject of young specialists who were in financial stress. As one of the doctors concerned, I wish to emphasize how urgent is the necessity for relieving this stress as quickly as possible.

I am 30, qualified six years ago, and began medical training twelve years ago. After three years in the Services and with a wife and two children I now earn £650 in a Class III Government grant. Even with the most careful living and considerable self-denial I find that I must borrow a considerable sum each year to maintain this frugal existence for myself and family. Since July 5 our plight is worse, as superannuation and national insurance take approximately another £3 a month.

As mentioned by Dr Clapham Coates (*Supplement* Sept 4 p 105) we are also interested to know how much better off we shall be when new rates of pay are announced. It is not unusual for us to find that a person who has not served in the Forces and who has qualified after ourselves has now reached specialist status as an assistant physician. It is also not unusual to find that a doctor qualified since the end of the war and now starting specialist training is earning as much as ourselves. Their success is well deserved but, denied of their opportunities because of war service we cannot but be envious. The remedy does not lie in placing us without the qualifications in their posts but in giving us the opportunity to continue training without financial embarrassment. The Spens Report in fact recommends this state of affairs. But it must be clear that security for a newly qualified doctor starting specialist training can be achieved at £600 a year but cannot be achieved at that figure after three years in the Services and with a wife and two children. What of the man with six years' service and four or five children?

Let us be given the financial security of a doctor who has not served. This must mean that years served in the Forces must be allowed to count as years of training as far as payment is concerned, but not, of course, of necessity for the granting of hospital posts. We shall still complete training, and so reach high remuneration, later than the non serving specialist but let us at least have financial security in the meantime. May this arrangement come quickly—I am, etc.,

EX SERVICE

## POINTS FROM LETTERS

## Free Medicines

DR T M CUTHBERT (Worthing) writes. Although I am entitled to receive medicines, etc., free, yet, because I am a retired practitioner, every time I require any medicine, etc., I must either trouble a fellow practitioner to write me out a prescription or pay for the medicine, etc., myself. Is this fair?

## RECRUITMENT OF YOUNG PRACTITIONERS

The Central Medical War Committee has been informed that on the recommendation of the Medical Priority Committee, the Minister of Health, with the concurrence of the Secretary of State for Scotland, has decided that the emergency arrangements under which a young practitioner liable for military service is recruited after a six months tenure of an "A" post will cease at the end of October. Young practitioners completing their tenure of "A" posts on or after Nov 1, and selected for appointment to "B2" posts, will be granted deferment of call up in accordance with the regulations in operation before the introduction of the emergency arrangements last July. Hospital authorities are being informed by circular letter of this change in procedure. There is, however, no change in the arrangement under which young practitioners approaching the age of 26 on qualification are recruited before their twentieth birthday, even if this should prevent their completing an "A" post or occupying an "A" post at all.

## RETURN TO PRACTICE

The Central Medical War Committee announces that Mr Gilbert Parker, FRCS(Ed.), has resumed civilian practice at 25, The Crescent Linthorpe, Middlesbrough (Middlesbrough 88945).

## Association Notices

ELECTION OF MEMBERS OF THE COUNCIL BY  
BRANCHES NOT IN GREAT BRITAIN AND  
NORTHERN IRELAND

Notice is hereby given that *nominations* of candidates for election as members of Council by the following grouped Branches for the period of three years, commencing from the termination of the Annual Representative Meeting, 1949 must be forwarded in writing so as to reach the Secretary not later than Jan 29 1949.

	Number of Members of Council to be Elected by Group
Branches within the area of the Medical Association of Eire	1
South Australian, Tasmanian, Victorian, and Western Australian	1
New South Wales and Queensland	1
New Zealand and Fiji	1
Barbados, Bermuda, British Guiana, British Honduras, Grenada, Jamaica, Leeward Islands, St Lucia, and Trinidad and Tobago	1
Aden and Ceylon, and Grouped Branches in India and Pakistan	1
Hong Kong and China, and Malaya	1
Cyprus, Egyptian, Gibraltar, Kenya, Malta, Mashonaland, Matabeleland, Mauritius, Northern Rhodesia, Nyasaland, Sierra Leone, Sudan, Tanganyika, Uganda, and Zanzibar	1

Nominations must be signed by not fewer than three members of any Branch in the Group and should be in the following form.

We, the undersigned, hereby nominate (full name and address to be given) for election by the (state the names of the Branches in the Group) Branch as a member of the Council of the Association for the three years 1949-52.

Signatures and addresses of three nominators  
Branches

Date

A notice will be published by the Council in the *Supplement* to the *British Medical Journal* of Feb 12, 1949, as to the nominations received in respect of each Group.

Where contests occur, voting papers containing the names of all duly nominated candidates will be issued from the Head Office, British Medical Association, Tavistock Square, London WC1, to each member in the Group.

By Order,

CHARLES HILL  
Secretary

## WEST DERBYSHIRE DIVISION

Notice is hereby given by the Council of the Association to all concerned of the formation of a new West Derbyshire Division comprising the urban districts of Matlock, Wirksworth, Bakewell, the rural district of Bakewell, the civil parishes of Dethick and Lea and Holloway.

The new Division will form part of the Derbyshire Branch.  
CHARLES HILL  
Secretary

Diary of Central Meetings  
OCTOBER

27 Wed Council, 10 a.m.

## Branch and Division Meetings to be Held

BATH DIVISION—At Royal United Hospital Bath Tuesday Oct 19 8.30 p.m. Dr Philip S. Hench (Director, Arthritis Unit Medical Clinic) 'Psychogenic Rheumatism'.

DARTFORD DIVISION—At West Hill Hospital (County Hospital) Dartford Friday, Oct 15 8.45 p.m. Mr Rodney Mangot 'The Management of Patients with Peptic Ulcer'. A discussion will follow.

SOUTH WEST ESSEX DIVISION—At Thorpe Coombe Maternity Hospital, Forest Road, Walthamstow London E Wednesday Oct 20, 8.30 p.m. Mr Alan Brews 'The Commonplace and Rare in Gynaecology'.

WESTMINSTER AND HOLBORN DIVISION—At Royal Cancer Hospital Medical School, 24, Onslow Gardens Fulham S.W. Wednesday Oct 20, 8.30 p.m. Mr A. Lawrence Abel 'Cancer of the Rectum'. Open to all medical practitioners in the area of the Division.

LONDON SATURDAY OCTOBER 23 1948

## THE SIGNIFICANCE OF PROTEINS IN NUTRITION THEIR PARTICULAR IMPORTANCE DURING CONVALESCENCE\*

BY

D P CUTHBERTSON, M D, D Sc

Director Rowett Research Institute Aberdeen

The protein component in nutrition is one of the most fascinating of all fields for study, for it deals with the essential fabric of growth, repair, and reproduction and with other dynamic expressions of vital activity involving continuous chemical change such as the maintenance of the osmotic relationships in the tissue fluids, immunity mechanisms, enzyme systems, and hormones

### Quality

There are some 23 different amino-acids in the body, and these are built up into the tissue proteins in the varying linkages and groupings which give to the tissue proteins their peculiar properties. These proteins thus subserve in some way or another the structural and functional requirements of the body, and variations in functional activity are coupled with greater or lesser difference in amino-acid make up of the proteins concerned. Proteins subserving the same function in various species have differences in the proportion or arrangements or even in the numbers of these different amino acids. Thus Williamson (1944) has shown that the proteins of human and cows' milk differ in the proportions of certain of the amino-acids, tryptophan in particular, and Mellander (1945) has shown that the caseins of human and cows' milk vary in their phosphorus content. The contradictory reports about the nutritive value of haemoglobin are apparently due to variations in the amino-acid composition of the haemoglobins of different species. Dog haemoglobin is deficient in methionine but not in isoleucine, while the reverse holds for human haemoglobin (Brand and Grantham, 1946). Prosthetic groups of carbohydrate origin—e.g., as in the pneumococcal antigens—or of lipid (see Cohn *et al.* 1944) may give additional specificity to the proteins.

The proteins of our food are the exogenous source of the amino acids or specific groups required by the body, and as a group they are relatively stable, though liable to suffer a slight change in molecular character on treatment—namely, the process of denaturation—which generally makes no appreciable difference in regard to utilization of the particular protein, although this physico-chemical change is of great assistance in cooking and baking. I need only instance the vast array of appetizing egg dishes, curds and cheese and the texture of bread as examples of this.

Following ingestion, the proteins are digested by the hydrolytic proteases of the alimentary tract, the amino acids so formed are then absorbed. There is some evidence that certain peptides or even larger fragments are absorbed

in small quantity as such. While the body has the faculty of synthesizing certain of these amino-acids or specific groups, others either cannot be synthesized at all or only at a very slow rate. Diets must therefore contain proteins which, when acting in supplementary fashion, will provide all the essential amino-acids required and sufficient nitrogen to provide for general purposes. It is very necessary that no key amino-acid be lacking, otherwise it will form a limiting factor in growth or even in maintenance. Dissociation in time of ingestion of the essential amino-acids, even though all the necessary ones are provided within the 24 hours (Henry and Kon, 1946), has been demonstrated to lead to inefficient functioning, as all are required at the same time. Further, dissociation in time of ingestion of protein and carbohydrate leads to an inefficient use of the protein (Cuthbertson and Munro, 1939, Cuthbertson, Munro, and McCutcheon, 1940). Better utilization is also obtained when the day's intake is spread over a number of meals than when it is divided over only two meals.

During the 1914-18 war, and in the years which followed, it became customary to divide dietary proteins into two groups, depending on the degree to which the proteins conformed to the then known requirements of man. It became the practice to regard the edible proteins of animal origin (gelatin as the main exception) as being in the first-class category and those of vegetable origin as second-class. These decisions were based on a few incomplete analyses and biological tests of the pure proteins rather than of the mixed proteins of the foodstuffs concerned. Nevertheless, this division was useful and served its purpose in drawing attention to the differences in amino-acid composition.

As the result of careful observation upon himself Corry Mann (1935) obtained evidence which suggested that there were pronounced differences in the biological value of such first-class proteins as those of meat and milk, and that the most likely explanation of his results was to be found in the superior quality of the milk proteins. Credit for pointing out the supplemental action of the proteins, not only in individual foodstuffs but in the diet as a whole, rests mainly with Mitchell (1924) and Terroine (1936). The natural selection of foodstuffs, even when entirely of vegetable origin, seems to permit adequate supplementations, but it is necessary to note that cereals tend to be low in lysine. The terms first- and second-class protein as applied to the mixed proteins in animal and vegetable proteins would appear in this sense to be meaningless provided there is sufficient protein in the diet and that the caloric requirements are fully met. Nevertheless the protein-rich animal foodstuffs are in part the vehicle of our intake of many vitamins, particularly the fat-soluble, and of many essential

\*Read in opening a discussion in the Section of Nutrition at the Annual Meeting of the British Medical Association, Cambridge, 1948.

minerals. The full story of their contribution to the diet has not yet been completely unfolded, and the significance of natural selection in this sense must be explored.

In addition to the major differences in amino-acid composition which characterize the proteins, minor differences in the nutritive value of the proteins of a single foodstuff can be induced by certain natural and artificial means. The studies of Everson and Heckert (1944) have demonstrated that the growth-promoting qualities of legumes seem to vary with the source, the degree of inactivity of the seed, and the method of cooking used. These observers found that all the mature legumes, except peas, were improved by the heating procedures employed. Severe heat treatment of wheat and oat cereals during certain forms of processing confirm the detrimental effects noted by earlier workers (Murlin *et al.* 1938, Stewart *et al.*, 1943). More recently Melnick *et al.* (1946) have shown that the biological value of soya and oat flours and of milk processed in different ways is related to the rate of release of amino-acids, particularly methionine, during digestion. Treatment of proteins during processing or cooking may thus alter the biological value of the product.

Mellanby (1946) has made the very important discovery that wheat-flour "improved" by the agene process, involving treatment with nitrogen trichloride, produces canine hysteria or, as it is called in the U.S.A., running fits when given as food to dogs. More recently ferrets have been shown to be susceptible (Mellanby, 1947). Mellanby considers that a toxic factor is produced in association mainly with the gliadin and glutenin fractions, and that the clinical signs are not due to a deficiency disease. Moran (1947) has also provided evidence against the deficiency theory, and has shown that not only the gluten fraction of flour but also certain other, but not all, proteins are capable of giving rise to canine hysteria when similarly treated. Further observations by Moran and his colleagues (Bentley *et al.* 1948) have indicated that methionine has a unique capacity to react with nitrogen trichloride, but that other amino-acids may also be implicated.

#### Protein Allowances for Health

The term "allowance" has come to be used in place of "requirement," as no satisfying data exist to provide us with a real knowledge of actual requirements.

Protein is man's chief source of nitrogen and sulphur, and the rate of supply obviously conditions growth, maintenance, repair, reproduction, and lactation. This is its primary function. It can also serve as a source of energy, but in this respect it would apparently be no more useful than carbohydrate and fat, unless its simultaneous metabolism with these substances is advantageous, or unless in virtue of its specific dynamic action under certain conditions it is peculiarly suited for those exposed to cold.

It may well be that our intake of protein-rich foodstuffs is also bound up with a need for those other essential nutrients contained in these foodstuffs and with the improvement in palatability and attractiveness of the diet which results. It is therefore possible that for these reasons we take in more protein than is strictly necessary, and also to safeguard against any special requirements that may arise. Very few diets exist in which the proportion of the calories derived from protein falls below 10%, and the level for a particular population tends to remain constant at all ages (except infancy) and at all grades of muscular activity. On the whole, people eat more or less of a mixed diet according to energy requirement.

If those races which are by circumstance predominantly carnivorous are excluded, then the percentage of the total energy derived from protein before 1939 lay generally

between 10 and 14%, and, whenever economic circumstances permitted, the intake of protein of animal origin was raised to the region of 60% of the total protein. How far this qualitative change is bound up with a real need for animal protein of a high biological value without requiring too much variety in foodstuffs, as in the case of the vegetarian, or for other dietary essentials associated with protein in these animal foodstuffs, is impossible to say. There is no doubt that the more attractive flavour and culinary properties of animal protein and its more easy assimilation are contributory factors, but it is possible for people to live and reproduce on diets containing little or any protein of animal origin.

To approach the problem from the experimental side is also very unsatisfactory. There have been three different types of assessment.

- 1 This is based on the requirement to replace the spontaneous endogenous nitrogen expenditure, together with the requirements for the laying down of any fresh tissues or the expansion of existing tissues or for milk production. A correction is then made for the biological value of the proteins used. Such work is of considerable interest, but involves experimenting under highly artificial conditions. Generalization of dietary requirements from such data cannot be viewed with equanimity.

- 2 Nitrogen-balance experiments in which nitrogen equilibrium is established at low intakes of protein. The values obtained are thus maintenance requirements but are again the result of a restricted regime. To convert the maintenance requirements into "standard" allowances an empirical 50% has been added by some workers. The scale of this empirical addition is undoubtedly influenced by that required to bring the values in line with customary feeding habits.

- 3 Tests to determine experimentally the point to which protein intake can be reduced without any impairment to health and physiological efficiency. Such experiments being of long duration become monotonous, and psychological difficulties complicate the issue. Further, children and pregnant and nursing women cannot be subjected to such tests.

In the present state of our knowledge I believe that it is much safer to view our allowances in terms of the dietary habits of the best-nourished section of the community and to pay particular regard to the proportion of the total calories derived from protein. This gives us a measure of protein allowance which is safe. It may be regarded as providing too much protein at higher levels of energy intake, but, as the protein intake naturally rises *pari passu* with the calorie intake, it would in any event be extremely difficult to alter natural selection.

There is evidence that the physique of children is improving—Tuxford (1942) has had to alter his index of malnutrition in the course of a quarter of a century, therefore, by basing protein intake on energy expenditure for age rather than directly on age, changing levels of intake are safeguarded.

On the basis of their study of children from 1 to 17 years whose restriction in food selection was at a minimum, Holt and Fales (1921, 1922) found that protein averaged 15% of the calories. Gephart's (1917) investigation of adolescent boys in a private school in America indicated that 15% of the calories were derived from protein. Wait and Roberts (1933) obtained a value of 12.4% for adolescent girls living in institutions in the same country. Polteva *et al.* (1935) found that in Russia the corresponding level was 13%.

Widdowson (1947), from her study of the individual diets of children—largely "middle-class"—found that one of the most constant features of the diets was the constancy of the percentage of the total calories derived from protein by children of various ages. The average levels for each age group fell within the range of 11 to 14%.

With regard to infancy, little can be said with confidence except that during the suckling period, when growth is most active and when presumably a perfect mixture of proteins is being consumed, the percentage of the total calories derived from protein ranges from 6 to 9%, according to the analyses quoted by the different authorities concerned. Adding 50% to the 9% gives 13.5%, which might safely cover the requirements of the weaning period and the next 12 months. Cows' milk has some 20% of the calories present as protein.

It should be noted that during the current period of sugar and fat restriction the percentage of calories derived from protein occupies a slightly greater proportion of the calories than was the case in more normal times. It is in the region of 12 to 14%.

It is suggested that an investigation is necessary to determine the level of caloric requirements by ages from 0 to 21 years based on the smoothed-out curves of the best data available for the best-nourished section of the child and adolescent population (Widdowson's might well serve as a basis unless some better data are available) and then to calculate the corresponding allowances for protein as described in the foregoing paragraphs. Similarly the various categories of adults can be treated, probably placing pregnant women during the latter half of pregnancy and nursing mothers at the upper end of the range.

### Protein Deficiency

If the diet is insufficient in energy value, and if energy expenditure is not reduced, proteins which would have been available for growth, maintenance, or reproductive functions may be deflected to meet the energy demands. After the first day or two of starvation some 13% of the calories expended by the body are derived from protein, the rest from fat. The addition of carbohydrate or fat spares this wastage of body nitrogen which occurs on diets that are inadequate in energy. When carbohydrate or fat in excess of energy requirement is added to a normal diet a considerable storing of nitrogen and sulphur takes place (Cuthbertson and Munro, 1937). How long this goes on is uncertain and may depend on the body's facility to raise its metabolic rate. This may well be a highly individual characteristic and account for differences in energy intake by persons of apparently similar build.

At one time it was thought that the proteins could wax and wane in molecular structure without serious alteration in property, but it is now known that the large number of different proteins found in the body remain true to type, and that while alterations in the quantity and quality of protein in the diet or fluctuations in its energy value do not apparently induce the body to form imperfect or unusual proteins they may influence the total or relative amounts of the different proteins in the tissues or tissue fluids. But this does not mean that the proteins, even of the fabric of the body, are in a stable state. The work of Schoenheimer (1942) and his collaborators (Heidelberger *et al.* 1942) has demonstrated that this apparent stability is in reality a dynamic equilibrium in which the proteins are participants in a constantly changing metabolic mixture and in which carbohydrates, fats, and other compounds take part.

For a long time it was thought that there was a store of protein in the body like that of fat in adipose tissue, but the search revealed only some waxing and waning in liver cytoplasm. The easily lost fraction of liver cytoplasm has been called "labile liver cytoplasm" in contrast to the "remaining liver cytoplasm" (Kosterlitz and Campbell, 1945-6). The view is now held that the body has the capacity to lose and replenish again its protein content by the increase or decrease of the existing and characteristic protein components of these tissues. The observations of

Upadhyay (1944) have shown that an intake of protein is sufficient to prevent anaemia in the non pregnant but may be insufficient when she is pregnant. Due must be taken of the hemodilution of pregnancy.

In general it may be said that from the dietetic point deficiency of protein intake is generally coupled with deficiency in calories. Evidence of these combined deficiencies were found only too often in the prisoners of war and political prisoners in the hands of our enemies in Europe and the Far East. The investigations of Keys and his collaborators (1946) on normal men subjected to a profound restriction in caloric intake has added considerably to our knowledge.

Vaughan, Dent, and Pitt-Rivers (1945) found that the best vehicle for administering protein to starving subjects was skim milk rather than a hydrolysate of casein but that occasionally it might be necessary to give intact protein by vein as plasma or serum.

Jorpes, Mignussou, and Wretling (1946) seem satisfied that an enzymic hydrolysate of casein fed as a supplement to breast milk produces an accelerated weight gain over breast milk alone. Loehle (1946) advocates the value of human plasma by mouth as the sole nutrient for the first day of life for premature infants and of plasma in addition to other foods thereafter.

Four types of diet for babies have been tested out by Albinese *et al.* (1947)—namely an evaporated milk mixture, a mixture based on an enzymic digest of casein, a similar digest of lactalbumin and in each digest of casein supplemented with tryptophan and cystine. The retention of nitrogen and the weight gain of the infants while on the acid digest of casein mixture were respectively about 70 and 50% lower than those obtained when the same subjects were given synthetic diets based on enzymic digests of casein or lactalbumin. The biological value of the enzymic digest was about the same as the evaporated milk mixture. It is thought that the acid digest of the casein lacks certain peptide like substances ("strepogenin").

### Plasma Proteins

Oedema is a frequent concomitant of a diet low in calories which thus causes a relative or absolute deficiency of protein. Keys *et al.* (1946) produced it experimentally in 34 normal men who lost a quarter of their body weight while subsisting for six months on a European type of semi starvation diet consisting of whole cereals, potatoes, turnips etc. providing an average of 40 g of protein daily. Pitting oedema appeared within two months in some of the men and eventually in all but a few. The ratio of extracellular water to cellular water was doubled. It is of interest to note that this development of oedema was accompanied by only a slight decline in plasma protein concentration averaging 0.73 g per 100 ml. Meanwhile the venous pressure had fallen to some 50% below normal. The evidence seems to indicate that it is not simply a result of hypoproteinaemia or of renal or cardiac abnormality. It should be noted that the hypoproteinaemia only predisposes to oedema, and that where dehydration is superimposed it may not be seen until treatment with fluid begins.

Anorexia is a potential and sometimes direct cause of insufficient food intake. It is well known that when there is a deficiency of an essential amino acid in the diet of experimental animals anorexia often ensues. Diarrhoea or undue intestinal hurry may be a cause of impaired absorption of amino acids. Experience at Belsen concentration camp indicated that hydrolysed protein passed largely unabsorbed through the guts of many of the inmates.

The work of Whipple (1942) has emphasized the part played by the plasma proteins in relation to protein

abolism, and recent experiments have shown that in experimental dietary deficiency some 30 g of albumin are needed for each 1 g of albumin in the circulation. This dynamic equilibrium between plasma protein and tissue protein means that a fall in plasma albumin concentration of 1 g per 100 ml implies a loss of protein of over 1 kg. In terms of actual muscle this is equivalent to 4 kg. In pregnancy, but more particularly in lactation, there is an increased demand for protein which must be met by an increased intake of food. The development of the mammary gland and its ability to secrete milk is determined by the food intake during the period of mammary development. This my colleagues have shown to occur in sheep. The effects of deficient intake of food during the latter half of pregnancy increased the number of neonatal deaths, and deficient lactation caused many deaths within the first 72 hours after parturition especially in the case of twin lambs.

Not all proteins appear to be equally useful in the maintenance of a normal level of protein in the plasma (Madden and Whipple, 1940, Whipple, 1942). Per unit of protein fed, beef serum will favour the production of three times as much plasma protein as beef heart, and more than five times as much as beef stomach, there is thus a qualitative as well as a quantitative aspect to the influence of animal proteins. Casein and lactalbumin have also high potencies. Animal protein is twice as effective as vegetable protein in combating oedema and hypoproteinaemia. Under certain conditions sulphur-containing amino acids occupy a key position in the synthetic process (Whipple, 1942, Himsforth, 1946).

The evidence points to the liver as being of primary importance in the production of plasma proteins, although some globulins may be produced elsewhere. The association of hyperglobulinaemia with proliferation of the reticulo endothelial system suggests that certain of the globulins of the plasma may possibly arise in that tissue.

Factors adversely affecting protein nutrition, such as direct or indirect starvation, haemorrhage, etc., lead to a fall in the plasma albumin while the plasma globulin is but little affected. These changes may affect the plasma proteins of the foetus as my colleagues have found in the case of the sheep. The relatively small size of the albumin molecule permits leakage in conditions of increased permeability—e.g., inflammation. Albumin is apparently synthesized more slowly than globulin, and mild damage to the liver seems to affect its formation. Where the protein intake is satisfactory and yet there is a fall of albumin due to deficient formation or loss from the circulation there may occur a slow, apparently compensatory rise in the globulin, probably to offset the lowered osmotic pressure due to the plasma protein.

#### Haemoglobin

Hahn and Whipple (1939) have clearly demonstrated that by limiting the protein intake in anaemia haemoglobin production can be reduced. When the erythrocytes disintegrate, much of the globin is saved and is probably used again to form a new haemoglobin or to supply some other protein needs of the body. Infection and to some extent nephritis in its later stages (Whipple, 1942) modify haemoglobin production. Robschert-Robbins, Madden, Rowe, Turner, and Whipple (1940) have found that in dogs given an abundant supply of iron, but fed to maintain a blood level of about one-third normal, two to three times as much haemoglobin was produced as plasma protein even when the stimulus was apparently maximal.

#### Protein Regeneration following Partial Starvation

The pattern of recovery of the blood proteins following extreme protein insufficiency has been described by

Rossiter (1946). In his study of Indian prisoners of war who had a normochromic macrocytic anaemia at the time of their liberation he found a reduced serum protein concentration coupled with their reduced body weight, the former being almost entirely confined to the albumin fraction of the plasma proteins. There was also a reduction in the total circulating haemoglobin as well as in the total circulating plasma protein. When these ex-prisoners of war were given a diet rich in calories, protein, and vitamins the above factors returned to normal according to a definite pattern. The first stage, lasting up to four weeks, was characterized by a rapid rise in plasma volume to normal and the disappearance of oedema. The improvement in the haemoglobin and haematocrit reading was not so rapid but the red cells quickly became less macrocytic. The total circulating plasma protein increased, but because of the rapid rise in plasma volume the plasma protein concentration changed but little. More albumin was formed than globulin.

The second stage (2 to 12 weeks) was characterized by a rise in plasma volume to well above normal. There was also a rapid increase in body weight and in total circulating haemoglobin and plasma proteins. The total circulating albumin increased more rapidly than the globulin, but the latter did eventually reach figures in excess of normal. The third phase (8 to 16 weeks) was marked by a return to normal values.

#### Immunity

The evidence is fairly conclusive that antibody properties are associated with specific modifications of the globulin molecule, but the definition of the relation between plane of protein nutrition and antibody response is by no means as clear as some workers would make out. Antibody production during active immunization appears to be a continuous process of production and shares in "labelled"  $N^{15}$  which has been added to the diet. On the other hand, passive antibody formation during passive immunity seems to have little relation to dietary nitrogen (Hcidelberger *et al.*, 1942). How far antibody formation is affected by competition for available amino acids in conditions of protein under nutrition is not quite clear. It would appear that in animal experiments severe hypoproteinaemia is coupled with a loss of ability to produce antibodies of several kinds (for review see Cannon, 1944), but in man conditions seldom develop which cause a pronounced reduction in the level of globulin in the blood.

My colleagues, Dr J W Howie and Dr E I McDougall have confirmed in the sheep that there is a direct correlation between the rapid decrease in globulin level and antibody titre in ewes' colostrum in the first few days after lambing, and that there is a correlation between the absorption of globulin and antibody ingestion of colostrum by the newborn lamb—a specialized phenomenon which has no parallel in later life. They have further found that the proteinuria of the newborn lamb after ingestion of colostrum is essentially globulin, and it retains the specific antibody properties of that developed in the mother in response to the particular antibody used.

#### Convalescence

Convalescence is the recovery of health and strength after illness. The illness may have been of sudden or insidious onset, it may have been the result of infection, abnormal metabolism or growth, or trauma, it may afflict the healthy, or it may supervene when the individual is poorly nourished.

On the surgical side protein depletion may also result from conditions affecting the ability to ingest, digest, and absorb sufficient food, and it may also occur as the result

of disuse atrophy, infection, and as a consequence of trauma, which includes surgical operations, fractures, dislocations, and burns. One, if not the main, problem of convalescence is the restitution of tissue loss. On the medical side protein deficiency may result from impaired digestion and absorption, excessive catabolism in fever, impaired synthesis in liver disease and loss in certain types of nephritis, ascites, and haemorrhage. Reference will now be made to a few out of many clinical states. No reference will be made to liver diseases in relation to protein intake, as Dr Glynn will deal with this aspect.

### Trauma

The protein depletion which follows moderate to severe injury is due essentially to two or more of five main causes: (a) loss of actual tissue; (b) loss of blood or exudate from the damaged area; (c) loss due to excessive protein catabolism which normally follows injury and subsequent surgical manipulations; (d) loss due to infection if that is superimposed; and (e) disuse or reflex atrophy (Cuthbertson, 1947).

During the period of traumatic shock there is a pronounced reduction in anabolism and catabolism. This then gives way to what seems to be a generalized catabolic phase coupled with local anabolic activity at the zone of healing. In injuries such as fractures, dislocations, and even meniscectomies the protein loss is generally due to two factors: atrophy and excessive catabolism of body protein (Cuthbertson, 1932; Berthel, 1947). Of these two factors the excessive catabolism of protein, which reaches a maximum usually between the fourth and eighth day in injuries due to direct violence, constitutes the major cause of protein depletion. Following the peak of nitrogen loss there is a gradual decline, though subsequent surgical procedures may cause further disturbance. Even after a month there may still be a slight negative nitrogen balance, but normally there is a slow merging into a general anabolic phase (Schenker, Stevenson, and Browne, 1946). In burns all five causes generally operate to produce a considerable loss of body nitrogen. In man the negative nitrogen balance in the first ten days after a fracture of the leg may amount to a loss of as much as some 856 g. of protein or 8% of the total body protein (Cuthbertson, 1932). This is some three to four times the total protein content of the liver. Although it would appear that this organ cannot be the source of the material catabolized, nevertheless it may play a vital part in the catabolic path of material supplied to it from other tissues. Occasionally this catabolic phase is not seen or occurs only to a small extent.

Disuse atrophy, though a contributory factor, does not provide an adequate explanation (Cuthbertson, 1929; Keys, 1944). The increased catabolic processes are more general than local, and seem to be conditioned by a reflex mechanism which leads either to the raiding of the body protein reserves in order to supply endogenously the necessary substrate of amino acids or peptide groups for the reparative process or to a mobilization of oxidizable material for the enhanced metabolism of the healing process. The fact that there is a parallel rise in the excretion of nitrogen and sulphur, at least in fracture cases, suggests that there is not a preferential retention of the sulphur-containing amino-acids. It has been suggested that the reflex exists in order to render the healing process independent of food supply (Cuthbertson, 1932). The so-called "toxic destruction of protein" in fever may be explained in this teleological fashion. Wild animals when ill or wounded seek security in hiding until they recover or die. The innate reparative processes must operate irrespective of an exogenous supply of energy or repair material.

When an animal has been depleted of its protein reserves no increase in the rate of loss of body protein occurs on fracture (Munro and Cuthbertson, 1943). Madden and Clay (1945) have shown somewhat the same effect in acute sterile inflammation. The greater the proportion of protein in the diet before and after injury, the greater the nitrogen loss (Munro and Chalmers, 1945). Browne *et al.* (1945) have also noted the apparent absence of a catabolic response after operation or injury in persons in a poor nutritional state at the time of injury.

Attempts have been made to stem the catabolic loss of protein by (a) substantial increases in the energy and/or protein value of the diet, or (b) by administration of amino acids singly (e.g., methionine), as mixtures, or as hydrolysates given intravenously. The evidence is now weighted against methionine having an effect in diminishing the negative nitrogen balance in burns where the previous diet is not deficient in methionine but yet the loss of cystine is quite considerable (Griddle, Peters, and Wakelin, 1947; Sellers and Best, 1947; Meyer-Hirshfeld and Abbot, 1947). Emerson and Binley (1946) have reported a retention of nitrogen in a few cases in which the ten amino acids which are essential for the growth of the rat were given intravenously. An increase in the protein content of the diet did not apparently have a similar effect. But much more evidence is needed, and I am doubtful if there is any real merit in such lines of parenteral therapy when the patient's ability to ingest and absorb normal dietary proteins is not impaired.

### Pre-operative Treatment

Despite substantial increases in the intake of abundant protein-rich food by patients with moderate or serious injuries it was found that a negative nitrogen balance generally, but not always, exists at the height of the catabolic period (Cuthbertson, 1936). A similar situation has been reported in acute infections (Peters, 1944). I consider that there is no special need to worry unduly about the loss of nitrogen following injury in the previously well-nourished patient; its measure is rather a measure of the nutritive state of the organism in respect of protein. Where, however, the patient is debilitated before operation it is considered that the ingestion of a diet adequate in protein should be instituted before the operation for this re-alimentation is as effective or more effective pre-operatively than corresponding increments made available in the post-traumatic phase, because a condition of nutritional imbalance is usually present in the latter state.

Satisfactory nutritional preparation will undoubtedly extend the benefits of surgery to a group of patients who in the past have often been denied surgery on the basis that they were too poor a risk. Wherever possible the pre-operative steps should involve not only restoration of the water and electrolyte equilibrium but so far as is possible a high-protein high-carbohydrate diet fed, where necessary, by tubal methods. Skim milk powder has been shown to have many advantages as the principal source of protein in the pre-operative diet of cases in which there is difficulty in management. Vareo (1946) has described a regime for the pre-operative treatment of patients classified as "poor risks". Diet 1 consisted of 160 g. of protein, 407 g. of carbohydrate, 18 g. of fat (2,426 calories, 1.6 calories per ml. of fluid diet). Diet 2 consisted of 120 g. of protein, 409 g. of carbohydrate, 37 g. of fat (2,446 calories, 1.6 calories per ml.). This was a less tasty diet rendered suitable for feeding by a nasal tube.

In non-obstructive cases there is presumably adequate enzymic activity without having recourse to predigestion measures. The diets of Vareo have applications to the treatment of cases with neoplasms of the colon.

sigmoid, and rectum and of patients with burns Varco has suggested that when the loss in body weight is at least 5 to 10%, three to five days of proper treatment are sufficient. When the loss approaches 20%, 10 to 12 days of proper feeding are necessary, and three weeks are necessary when the loss approximates 25 to 30%.

A more recent prescription by Varco (1947) for a high-protein, high-calorie diet is made up of six whole eggs, two egg whites, 4 oz of skim-milk powder, 300 g of lactose or cane sugar, 1,000 g of skim-milk, and 5 gr (0.32 g) of salt, and is estimated to provide 2,446 calories and 120 g of protein in 1,500 ml. When this is the sole diet Varco recommends about 3 litres, equivalent to 4,900 calories. This recent line of treatment is very suggestive, although it does not yet provide concrete proof that such measures of nutritional readjustment can yield a margin of safety for the patient requiring surgery in spite of previous and co-existing deleterious influences on metabolic processes. The clinical evidence in support of this thesis is certainly worthy of consideration and confirmatory trial.

There is no doubt that too much stress has been placed on forced feeding of surgical cases. Those who have had clinical experience of burns know that it is almost impossible to force-feed patients during the first few days after injury, when fluid and electrolyte balances are becoming adjusted and the illness is at its height.

I have on many occasions stressed the limitations in the use of protein hydrolysate and would deplore much unsound physiology shown by many workers in this field of therapeutics who give the hydrolysate by mouth even when the patient can adequately hydrolyse intact protein. Although Cox and Mueller (1939), Elman and Weiner (1939), and many other later observers have recorded a measure of success with intravenous alimentation by protein hydrolysates and glucose, some using it as a means of total feeding, these preparations nevertheless possess some very distinct limitations owing to the large volumes which have to be given and the time taken—90 g of protein takes eight to nine hours and a volume of 2,500 ml (Elman, 1943)—the febrile reactions, nausea, and vomiting which may occur, and the thrombophlebitis which often results through prolonged intravenous treatment. Plasma and glucose are safer fluids. An extensive study of a mixture of the ten essential amino acids and glycine as an 8% solution has been made by Spence, Evans, and Forbes (1946), but the end-result is somewhat equivocal. Six-molar sodium lactate was given separately to provide a base when the amino-acids were given intravenously.

Subsequent operative procedures may accentuate the degree of negative balance, as the metabolizable material required for the processes of repair may necessitate a further breakdown of protein. This latter response is known to be conditioned by the nutritive state of the organism.

I consider that the immediate phase of protein catabolism is related to the healing process and should not be interfered with. There is little point in trying to supply the patient with food in excess of that which appetite dictates. In severe injuries involving prolonged convalescence every reasonable step should be taken to maintain, if not to extend, the patient's intake so as to make good the tissue losses. A diet of high energy and high protein content is required. An intake of 150 g of protein a day is often desirable. The amount of protein which is lost in extensive burning can be very great indeed (Cuthbertson, 1945).

### Fever

Leaving out of account external causes and certain peculiar forms of hyperthermia, fever generally arises from an infection or in a milder form as a result of trauma—

traumatic fever. In both forms the basal metabolism is increased. For every degree Fahrenheit rise in temperature there is a 7% increase in the basal metabolism. At the height of the fever appetite fails and the energy required comes from a utilization of the tissues. In addition to a loss of fat, an increased excretion of nitrogen, sulphur, and potassium occurs, indicating an actual breakdown of tissue material. The situation is rather analogous to starvation, where some 13% of the energy expended comes from protein and the remainder from fat. The destruction of protein is apparently due neither to the raised metabolism nor to the fever, for the protein breakdown in fever is greater than in normal subjects whose metabolism has been elevated to the same degree by exercise (Kocher, 1914) and is not induced by external sources of hyperthermia (Graham and Poulton, 1912-13). The hyperthermia in traumatic fever is generally very slight unless there is infection.

In *acute febrile illnesses*—e.g., pneumonia—the outcome is generally a matter of a few days, and the diet should be such as to save the patient from undue exertion. There is usually no need to worry about the actual amount of food eaten. It is sufficient to provide small and frequent feeds of milk or milk plus egg, sweetened fruit juice, and, later, light cereal dishes. Nevertheless, in the acute phase of certain infectious conditions, even although there is evidence of a catabolic phase, unless it can be shown that generous diets are injurious, efforts to feed such patients should not be abandoned.

In *long-continued fever*—e.g., typhoid fever—it is necessary to prevent undue loss of body tissue, and for this purpose the diet should have as high an energy and protein value as possible without causing ill effects. The aim is to try to secure an intake about 50% above the normal maintenance intake. A high carbohydrate diet has a protein-sparing effect, and it should be given in a readily digestible form—large meals being avoided. The protein intake should be such as to offset the catabolic loss of tissue protein which takes place particularly during the height of the fever. It should be noted that it is generally impossible to establish nitrogen equilibrium at this stage. Small semi-solid or fluid meals every two to three hours is a good regime. The protein required is readily obtained if two pints (1.14 litres) of milk are used daily. As the patient improves, the diet is modified by the addition of toast or bread with butter or margarine, milk puddings, custards, stewed or fresh fruit, chicken, rabbit, and fish. During convalescence it is wise not to push the patient to take quantities of food beyond his normal capacity.

### Diseases of the Kidney

Apart from rest in bed and protection from cold, dietetic measures constitute the most important part of treatment in acute nephritis. In subacute and chronic nephritis with oedema, massive proteinuria, and hypoproteinaemia, a properly constructed diet is of both symptomatic and general value. In chronic nephritis without oedema but with failure in renal concentrating power there is much less satisfactory evidence that dietetic treatment will delay to any considerable degree the final onset of uraemia. For this reason, and because of the chronicity of the disease, it is unwise to insist on premature or too rigid dietetic restrictions which may depress the patient and impair his strength without appreciably improving his primary lesion (Davidson and Anderson, 1947).

The aims in treating nephritis by dietary means are (1) to spare the diseased kidneys—particularly in acute nephritis, (2) to prevent uraemia—i.e., the accumulation of waste products, (3) to prevent oedema, which is caused by retention of water and salts, and (4) to maintain nutrition.

Apart from acute or subacute nephritis, or in states of renal insufficiency with marked nitrogen retention, the protein intake should be maintained at normal levels

## BRONCHIAL CARCINOMA\*

BY

R C BROCK, MS, F.R.C.S

Thoracic Surgeon to Guy's Hospital Surgeon to the Brompton Hospital

The surgical treatment of bronchial carcinoma is now fully established and is generally accepted as the most desirable treatment of this condition at our disposal. Indeed, the success of surgery has placed bronchial carcinoma among the curable diseases, in marked contrast to the position it held a few years ago, when its diagnosis was synonymous with a death sentence. At the same time it is still a terrible disease with a high mortality, and we must remember that operation is possible in only a minority of cases. Furthermore, the importance of the problem it presents can be realized when it is stated that it occurs nearly as often as carcinoma of the stomach and of the colon.

With the establishment of the successful surgical treatment of bronchial carcinoma it becomes more and more imperative that the disease should be recognized at an early date so that the patient can be referred to the surgeon while operation is still possible. The operative technique is now largely standard, and although there will doubtless be further improvements, notably in regard to a more radical operation, the surgeon's place in treatment is now largely defined. He is, however, powerless to effect a cure unless he receives patients suitable for operation; it is impossible for him to save the advanced case. It follows, therefore, that the most important task in the management of this terrible disease lies not so much with the surgeon as with the general practitioner and the consultant physician, who are usually the first to see these patients. Although the ultimate act of treatment is in the surgeon's hands, the greatest responsibility and the greatest chance of saving the patient's life unquestionably lie in the hands of the earlier medical attendants.

I have often thought, when contemplating a patient successfully operated upon, that his life has been saved not so much by surgery as by the doctor who first made the diagnosis and who directed him to a surgeon. For this reason I will give a simple presentation of the leading clinical features of the disease, and especially the early symptoms and signs, the part that surgery plays in described chiefly to emphasize the need for early diagnosis.

## Clinical Features of Bronchial Carcinoma

Bronchial carcinoma varies considerably in its pathology, in its clinical manifestations, and in the duration of the illness it causes. Occasionally one sees patients who have lived several years with the disease, more particularly elderly patients with a slowly growing squamous-celled growth. These are the exception, and it must be remembered that the average expectation of life from the time the patient first consults his doctor is no more than six months, therefore it is useless to spend three to four months making a diagnosis and to expect the disease to be still in a curable phase. This is especially true in the case of patients below the age of 50. It is almost a truism to-day to plead for early diagnosis in cases of cancer, but the urgency justifies the emphasis.

The most important step in making a diagnosis of any disease is to think of it. So often the patient with a cancer of the lung has been observed or treated empirically

\*Read in opening a discussion in the Section of Diseases of the Chest at the Annual Meeting of the British Medical Association, Cambridge, 1948.

Tudor Edwards (1946) found an operability rate of 7%. Some surgeons have published figures with a very high operability rate—e.g., Rienhoff (1944), 181 cases, 71 (39%) operable—but it is certain that in such series gross selection has occurred before the patients reached the surgeon. Even though in my own work I see a large number of cases without selection I am aware that the overall operability is less than that given above. The figures given by the British Empire Cancer Campaign (1943) of their investigations carried out in 1938, in which the operability was 14%, are too pessimistic and were almost certainly due to a paucity of expert surgical facilities. It is reasonable to state that the present operability rate of bronchial carcinoma is about 15%, and the indications are that this figure will continue to improve for a few years more.

### The Operation

The surgical treatment of carcinoma of any organ is based on a radical removal of the organ together with as wide a removal as possible of its associated lymphatic field. This has led to the employment of dissection pneumonectomy as the proper operation for bronchial carcinoma, for only in this way can one hope in most cases to remove the growth widely together with the lymphatic glands. Lobectomy is rarely possible or desirable, and many surgeons condemn it out of hand as a wrong operation. I would not go so far as this, because I have found that in properly selected cases it is still an operation of great value and one that can give good results. I still use it in certain elderly patients who are suffering from a peripheral or parenchymatous type of growth and in whom the hilum appears clear. I have in all used it 15 times in 101 operable cases and have been well pleased with the results, which compare favourably with those of pneumonectomy (Table I).

TABLE I—Results of Lobectomy

Died from operation	1
Died since operation	5
Survived 3 years	1*
18 months	1
under 1 year	3
Alive and well after operation	9
Over 7 years	1
3	3
2	3
1 year	1
Under 1 year	1

\* Suicide

Except for selected cases, however, radical pneumonectomy must remain the operation of choice. As with all operations, one evolves towards a more efficient and more radical procedure, and from simple dissection pneumonectomy we have progressed to intrapericardial pneumonectomy. If the pericardium is widely opened and that part of the sac surrounding the hilar structures is removed together with the lung, a much more radical, and often much easier, operation is possible. Lately I have extended the operation still further to include a complete block dissection of all the accessible mediastinal glands from the superior thoracic inlet down to and including those in and around the main bronchi and continuing down to the level of the diaphragm. This glandular removal includes all the associated connective tissue in the mediastinum. I have called the operation "block-dissection pneumonectomy." It is just as well tolerated by most patients as the usual simple extrapericardial dissection operation. It is of course not possible to make a complete removal of all the lymphatic field as the connexions are so widespread and complicated which is one of the reasons for the gravity of bronchial carcinoma. Moreover, there is always the peril of a blood-borne metastasis having already occurred. Block-dissection pneumonectomy is, however, the only logical evolution of surgical treatment, and time alone will prove whether it is

more effective than the less radical operations. I am at present engaged in a careful study of the glandular field removed at operation to try to correlate the condition of this with the ultimate fate of the patient. At present the results are based on a mixture of operations starting from the very early ones—often done rather falteringly in the early days, with a higher mortality and, doubtless as a result of the less complete removals done at that time, with a correspondingly greater tendency to earlier recurrence. My own figures as they stand at present are shown in Table II.

TABLE II—Results of Operation

No. of cases	101
Lobectomy	15
Pneumonectomy	86
Died from operation	18
Died since operation*	28
Survived 4 years	1
up to 3 years	3
2½	1
2	1
1½	4
1 year	6
6 months	12
Alive and well after operation	55
Over 9 years	1
7	3
6	2
5	2
3	10
2	7
1 year	11
Under 1 year	19

\* Three of these patients died from causes other than recurrence, the rest died of recurrence of carcinoma either in the chest or elsewhere.

Considering these figures represent an experience over some 15 years, during which approximately 1,000 cases of bronchial carcinoma have been seen, they make somewhat gloomy reading. Nevertheless it is possible to read a great deal of hope into them, seeing that without surgery scarcely any one of the 55 patients now alive and well would have survived, of the 28 who died since operation many obtained great benefit, a number enjoyed a useful extra span of life, and in many cases death came in a kinder form than would have been the case with the primary growth untreated.

Table III includes the largest groups of figures published by other surgeons, with my own series added.

TABLE III—Collected Figures of Operative Mortality

	No. of cases	Deaths
Edwards (1946)	70	12 (17%)
Graham (1944)	70	21 (30%)
Rienhoff (1944)	71	15 (21%)
Ochsner, Dixon and De Bakey (1945)	58	16 (27%)
Clagett and Brindley (1944)	43	14 (32%)
Sellers, Cruickshank and Billimoria (1947)	130	19 (15%)
Brook	101	18 (18%)
	543	115 (21%)

There remains much room for improvement, and, while a part of the responsibility for this must rest with the surgeon to better his technique and the efficiency of his curative operation, the greater responsibility rests with those who have the task of making the diagnosis or thinking of the diagnosis and referring the patient for expert investigation and treatment. In this lies the greatest hope of further improvement in our results.

## PRIMARY POST-PARTUM HAEMORRHAGE

BY

JAMES B JOYCE, MRCS, MR COG

AND

G GORDON LENNON, ChM, MR COG, MMSA

(From the Nuffield Department of Obstetrics and Gynaecology  
University of Oxford)

"All women, when the placenta separates, and after it is delivered, lose more or less red blood from the quantity of half a pound to that of one pound or even two, but should it exceed this proportion and continue to flow without diminution, the patient is in great danger of her life"

This description of post-partum haemorrhage was given by William Smellie about 200 years ago (circa 1751). Its truth is still plain to day, although we now customarily define abnormal haemorrhage as a blood loss that exceeds 20 oz (568 ml). Haemorrhage ranks next to "toxaemia" and "accidents of childbirth" in maternal mortality statistics, it is a more important cause of death in childbirth than sepsis.

## Present Investigation

During the period 1938-47, 156 cases of post-partum haemorrhage and 56 cases of manual removal of the placenta occurred in patients under charge of the Nuffield Department of Obstetrics, in addition, a considerable number of cases were dealt with by the "Emergency Obstetric Service" in answer to urgent summons by outside practitioners. An analysis of the results is now presented, but in regard to methods of treatment it should be noted that during the course of these years a progressive improvement took place in blood-transfusion technique, in the use of sulphonamides, and particularly in the increasing availability of penicillin.

In the second part of this paper an attempt is made to draw up a list of short and clear recommendations regarding the conduct of the third stage of labour in domiciliary practice.

## PART I

## Analysis of 156 Cases of Post-partum Haemorrhage

*Parity*—Primiparae numbered 94, multiparae 62

*Type of Pregnancy*—Normal pregnancies numbered 100. Of the remainder, 22 showed some form of pre-eclamptic toxæmia mostly mild. There were 4 cases of proved anaemia. Only one case of hydramnios was noted.

*Type of Labour*—Normal labour occurred in 113 cases, forceps deliveries numbered 27, other obstetric manoeuvres, such as version, insertion of bag, etc., were performed in 16. Medical or surgical induction was undertaken in 24. Multiple pregnancies numbered 3 and breech deliveries 4. Two patients with placenta praevia had post partum haemorrhage after vaginal delivery.

From these figures it will be noted that neither hydramnios nor multiple pregnancy figured prominently in the aetiology of post-partum haemorrhage. This is contrary to current teaching. Placenta praevia, another traditional cause of post-partum haemorrhage, contributed only two cases to the list, probably because patients with major degrees of placenta praevia were treated by caesarean section; the placenta was removed immediately, and the bleeding site was directly controlled.

*Length of Labour*—The average length of all the labours was 21½ hours, with extremes of 2¼ hours and 66 hours. In only 25 cases did labour last more than 30 hours.

*Amount of Blood Lost*—The blood loss before and after delivery of the placenta, estimated by the obstetrician or midwife, averaged 35 oz (990 ml). As many patients suffered from blood loss before as after delivery of the placenta.

## Methods of Delivery of the Placenta

	No	Average Duration of Third Stage
Expulsion by fundal pressure	105	30 minutes
Spontaneous delivery	27	15
Credé's expression	23	70
Retained placenta (found post mortem)	1	
Total	156	

*Credé's Expression*—Although Credé's method of expression was used in a relatively small proportion of all cases developing post-partum haemorrhage, the reverse of the picture—i.e., cases in which Credé's method was used without associated post-partum haemorrhage—is not recorded. No fair conclusion can therefore be drawn regarding the part played by this manoeuvre in causing or preventing haemorrhage or shock.

*Blood Transfusions*—The total number of transfusions was 38. The average amount transfused was 2 pints (1.4 litres).

*Time of Administration of Oxytocic Drugs*—In 113 cases an oxytocic drug was given after delivery of the placenta. In a small minority of cases (11) an oxytocic drug was given before the delivery of the placenta (ergometrine 8, "pituitrin" 2, "pitocin" 1). In the remainder the time of administration of the drug was unstated, but was presumably subsequent to the delivery of the placenta.

*Uterine Packs*—In no case was a pack inserted to control haemorrhage in this series.

*Puerperal Morbidity*—"Notifiable" pyrexia occurred in 17 cases. In the majority of cases this was attributed to urinary infection, birth-canal infection with known pathogenic organisms occurred in less than one third of the whole.

*Mortality*—There were two maternal deaths, giving a mortality rate of 1.3%. One of the patients who died was admitted as an emergency case with a retained placenta. She died before it could be removed. The other died from severe pregnancy toxæmia.

## Analysis of 56 Cases of Manual Removal of the Placenta

The following table gives details of these cases

Primigravidae	38
Multiparae	18
Spontaneous delivery of foetus	40
Emergency admissions	25
Notifiable pyrexia	19
Mortality	0

Regarding the incidence of "notifiable" pyrexia, there was a marked fall subsequent to 1942—only 5 cases out of 30. None of the patients received penicillin therapy, so the improvement may be shared by improved blood transfusion technique and improved sulphonamide therapy. Prophylactic penicillin therapy may further reduce the incidence of morbidity, but was not used in the cases now under review. A similar low morbidity rate recorded by Sewall and Coulton (1946) is attributed by them to the performing of manual removal before the patient had become grossly anaemic and shocked.

### Emergency Obstetric Service

The above 56 cases do not include any "flying squad" cases. These are analysed in the following table

Cases of Primary Post-partum Haemorrhage Emergency Obstetric Service 1946-7			
Traumatic post partum haemorrhage		1	
Haemorrhage after removal of placenta		21	
Retention of placenta		29	
Manual removal	21	8	
Manual expression		9	
Incomplete abortion		60	
Total		49	
Transfusions		45	
Blood		4	
Saline			

It will be noted that out of 60 summonses for primary post-partum haemorrhage 38 were directly connected with retention of the placenta

### Conclusions

In the hospital deliveries analysed post-partum haemorrhage occurred as often in primigravidae as in multiparae. It occurred as often after normal as after abnormal labours. Contrary to the usual teaching, there was no evidence that multiparity and hydramnios were prominently associated with post-partum haemorrhage. The puerperal pyrexia rate was high after post-partum haemorrhage. Urinary infections were the commonest cause of this morbidity.

In collecting and analysing these case records the opinion was formed that (a) manual removal of the placenta is a less dangerous procedure now from the point of view of sepsis than is generally supposed, (b) greater use might be made of ergometrine in the control of haemorrhage, (c) larger transfusions of blood might reduce morbidity and shorten convalescence.

### PART II

From the point of view of midwife and general practitioner we believe there is present need for clear recommendations regarding the treatment of post-partum haemorrhage. The following intentionally dogmatic statement is an attempt to remedy these shortcomings, and is based on the evidence presented in Part I.

#### Treatment of Primary Post-partum Haemorrhage

Before considering methods directed to the control of uterine haemorrhage we would emphasize that the bleeding may on occasion come from perineal, vaginal, or cervical lacerations. These may require suture.

Since so many cases of primary post-partum haemorrhage occur after normal delivery it must be supposed that the management of the third stage of labour is often mis-handled. The chief requirement is the exercise of patience, but an alert eye must be kept for deviations from normality in uterine function so that prompt and ordered action may be employed when necessary.

#### Management of the Third Stage of Labour

As long ago as 1767 John Harvie (Smellie's successor) stated, when discussing this subject, "Nature is to be assisted, to be followed and supported, but seldom or never forced."

To wait for 20 to 30 minutes in the expectation that natural separation and expulsion of the placenta will take place is still the best policy, and is the method favoured by the majority of obstetricians. The hand supports the fundus of the uterus throughout. It is not enough to keep a record of the patient's pulse and to ignore the abdomen, for the uterus may be actively bleeding and the fundus rising because of the retained haemorrhage despite the continuance of a relatively steady pulse rate. Sometimes the con-

dition is overlooked because a lower uterine segment alone distends and a contracted uterine body and fundus are felt at a high level in the abdomen.

The signs of placental separation and descent must be appreciated and not confused with the onset of post-partum haemorrhage. They are the rising of the fundus, the expulsion of a small quantity of blood, and the permanent lengthening of the cord. When, after these have occurred, the uterus contracts and the abdominal muscles are used, the placenta is expelled—aided, if necessary, by downward and backward pressure of the attendant's hand on the uterine fundus (Harvie, 1767).

#### Treatment by the Midwife

**Before Delivery of the Placenta**—(1) Provided that the patient's bladder is empty, the midwife should massage the fundus of the uterus to stimulate a contraction, separation and descent of the placenta should then occur. (2) If these do not occur and the haemorrhage continues she should give 0.5 mg ergometrine intramuscularly. She should not wait until the condition of the woman is grave before giving the injection. The time to have prepared this injection is just before the birth of the baby—intelligent anticipation. After the injection the midwife should again support the fundus of the uterus and expel any clots that have collected meanwhile. (3) The midwife will have sent for medical aid at the outset. This action is, of course, required of her, but it will obviously not arrest haemorrhage, and much time may elapse before the doctor's arrival.

**After Delivery of the Placenta**—(1) Massage of the fundus of the uterus (avoiding the region of the ovaries) should stimulate uterine contraction and so control bleeding. In addition, ergometrine 0.5 mg (if not recently administered) should be given by deep intramuscular injection. (2) If the haemorrhage is not controlled the uterus should be stimulated by bimanual compression. This can be made through the abdominal wall if the woman is thin, or by a closed fist in the vagina and an open hand on the abdominal wall pressing down the posterior wall of the uterus if the external method is unsatisfactory. This compression is difficult to maintain, but may tide over an urgent few minutes till medical aid arrives.

#### Treatment by the Doctor

**Before Delivery of the Placenta**—The initial treatment is the same as that recommended for the midwife. If the midwife has not already given ergometrine, the doctor should give 0.25 mg intravenously (Moir, 1947). He should be ready to "squeeze the fundus of the uterus like a sponge" (Stabler, 1947) in an effort to deliver the placenta with the strong contraction that almost invariably takes place 45 to 50 seconds after injection of the drug. His grip should be firm but not powerful enough to bruise the uterus. If he fails to expel the placenta there is no more to be done, as there will be a well-contracted uterus and also, incidentally, a contraction ring. It will be necessary to wait for more than half an hour to let the contraction ring relax before removing the placenta manually. It is improbable there will meanwhile be any further bleeding, and this time can be well spent in resuscitation of the patient and transferring her to hospital or making arrangements for the manual removal under anaesthesia in her home.

Instead of giving ergometrine the doctor may elect to remove the placenta manually, but, as this will require administration of an anaesthetic for most cases, he will find ergometrine more immediately available.

**After Delivery of the Placenta**—The treatment should be that recommended for the midwife except that the doctor will give the ergometrine part intravenously and part

intramuscularly Few cases will fail to respond to bimanual compression of the uterus, maintained if necessary for several minutes

### Retained Placenta—No Haemorrhage

We believe that a retained placenta should be removed not later than two hours after delivery of the baby (Sheehan, 1948) In some cases the maternal pulse rate rises although there is no haemorrhage If the third stage is being properly managed and the placenta is still retained after one hour, arrangements should be made for removing it as soon as possible Under general anaesthesia a gentle attempt is first made to express the placenta, if this does not succeed, manual removal should be done without further delay

### Technique of Manual Removal of the Placenta

After cleansing the vulva the bladder is catheterized The whole hand is introduced into the vagina (Stitches in the perineum ought not to have been tied) The tautened cord is palpated and traced upwards It is a guide to (1) the contraction ring of the uterus, if present, (2) the placenta, its site and extent (Fig 1)

FIG 1

The contraction ring may require stretching by gentle insinuation of the cone-shaped hand The placenta may already be separated and all that is required is its removal If the placenta has not separated, however, the hand is withdrawn to the lower uterine segment (Fig 1) and an attempt is made to get between membranes and uterine wall The placenta cannot be separated adequately unless the hand is external to the amnion and chorion Then we believe it is better to go to the highest point of the placenta and start separation from above downwards This allows the uterus to retract immediately on the sinuses opened by the manipulation Separation is best accomplished by scratching movements of the tips of the fingers directed always towards the placenta and never towards the uterine wall The other hand, placed on the abdomen, is of great help in pushing the fundus towards the hand inside the uterus After the placenta is completely separated it is removed in the palm of the hand, very slowly, to allow separation of the remainder of the membranes

Immediately on removal the maternal surface of the placenta is examined, and if a piece is thought to be missing the hand must re-explore But the best chance of removing the placenta completely is at the first attempt The ragged placental site may make re-exploration most confusing with regard to the recognition of retained fragments Ergometrine, 0.25 mg intravenously and 0.25 mg intramuscularly, is given on completion of the operation

**Difficulties**—(1) On introducing the hand the cervix may be mistaken for the contraction ring, and vice versa (Fig 1) (2) It appears that on rare occasions the contraction ring has been mistaken for the placental edge Here the thicker upper uterine segment joins the thinner lower segment, and separation has, in error, been attempted between the two, so that the hand is soon in the peritoneal cavity This would explain those cases in which manual removal of the uterus has been performed instead of manual removal of the placenta (Wassenaar, 1947) (3) A contraction ring may be situated in the cornual portion of the uterus, pre-

venting the escape of part of the placenta (Fig 2) separation of the placenta is accomplished from below upwards (Fig 2) a fairly large bleeding area is exposed before the contraction ring is felt, and as this constriction is a very much more difficult one to overcome, and is less accessible than the other type (Fig 1), there is unnecessary blood loss It is better first to reach the fundus of the uterus and diagnose this cornual contraction and deal with it It is in this type of case that the hand on the abdomen pushing the fundus downwards is of most value The whole placenta may be within this cornual contraction ring (4) There may be no line of cleavage between placenta and uterine wall This is the very rare condition of placenta accreta One of us has seen this in a case at caesarean section (Lennon, 1947) Possibly the best treatment is to leave the placenta and to cut the cord off short in the hope that a fragmentary discharge of the placenta will take place in the ensuing few weeks (Gemmell, 1947)

FIG 2

### Comment on Certain Alternative Treatments

Treatment of post-partum haemorrhage by use of a hot intrauterine douche has not been recommended because of the difficulty in adjusting the fluid to the correct temperature—a time-consuming task There is little margin between a douche hot enough to stimulate uterine contraction and one that will burn the skin The oxytocic drugs now available are far easier to use and are at least as efficient

Packing the uterus is difficult and requires special instruments if the pack is to reach the upper as well as the lower uterine segments Packing the vagina is simpler, but is still awkward to carry out in domestic practice and tends to cause shock, it may, however, be necessary if bleeding is due to a high vaginal or cervical tear

Hysterectomy is obviously not a possibility in domestic practice, and in all events should not be required in any but the most intractable cases of haemorrhage

Posterior pituitary extract has not been advocated for two reasons (1) it may cause shock on its own account, resulting in death (Adelman and Lennon, 1941), and (2) it is better for midwife or practitioner to know one drug (ergometrine) and its uses than to be confused in the use of two different oxytocics

It will have been noted that the name Credé has not been used throughout Part II This has been a deliberate omission We have had Credé's own description of his manoeuvre (1853, 1861) translated, and we consider that Harvie, ninety odd years before, gave a much better account of external manual expression of the placenta It is obvious that Credé did not wait for natural expulsion of the placenta, but in all cases immediately after delivery stimulated uterine contraction by manipulations through the lower abdominal wall, gripping the total uterus from outside with the hand so that his five fingers exerted a gentle pressure on all sides of its body and thus expelled the placenta

### Summary

A review of 156 cases of post-partum haemorrhage and of 56 cases of manual removal of the placenta is made

This analysis includes consideration of type of pregnancy type and length of labour blood loss, morbidity, and mortality The main findings are listed at the end of Part I of this paper

A routine for the conduct of the third stage of labour under normal conditions, and when haemorrhage occurs, is outlined

The technique of manual removal of the placenta is described and illustrated

the tendency to strangulation in women being almost three times as great. The frequency of strangulated femoral herniae to inguinal is also striking (25% and 2.6% respectively), and in the case of inguinal strangulation 76% occurred in men. Of the total number of femoral strangulations 7 were of the Richter type. The average age of strangulation was 64 for women and 63 for men, the overall mortality rate was 6 deaths in 45 cases, or 13.3%

## Incidence of Recurrence

Of the total number of cases admitted in the period 1942-6, 120 were personally examined and closely questioned about any disabilities following operation. The technique used was the low method of herniorrhaphy, and a careful follow-up revealed no recurrence in the 54 male patients, though there were four such recurrences in the 66 females, thus making an over-all recurrence rate of 3.3%. The cases were not selected in any way, and included strangulated as well as list cases, as previously stated, the ages ranged from 8 to 79. One of the recurrences was first operated upon in 1920, and at the time of the second operation the tissues were in a generally weak condition, but this has been counted in the present series, as it is a definite recurrence. Five other recurrent cases were successfully operated upon, and routine examination has shown no recurrence after periods varying from 2 to 5 years. In each of these cases a very definite sac was presented, and in four out of the six it did not seem to have been adequately removed at the time of the first herniotomy—a finding borne out by the fact that recurrence had taken place a few months after operation. It is certainly true that the most fruitful source of recurrence lies in failure to remove the sac adequately, the commonest mistake being to transfix the sac too low down and to omit to clean the neck thoroughly (a most important step, if indeed not the most important step of the whole operation), so that after excision of the sac retraction through the femoral canal cannot adequately take place, thus leaving the stump of the sac in the crural ring, which invites a further pouch of peritoneum to form, with ultimately the development of another hernia.

There appeared to be no increased likelihood of recurrence taking place in the aged as compared with the young, nor in relation to heavy work, and strangulated cases were no more likely to recur than the non-strangulated. Chronic chest conditions, too, seemed to have no ill effects, and one patient who suffered much from a severe and persistent cough (as he put it, his cough was so bad it knocked him out of bed) was found to be completely sound, so far as his hernia was concerned, when examined 2½ years after operation, at the age of 72. This is in contrast to inguinal herniae, where there seems little doubt that recurrence is favoured by heavy work, chronic cough, and similar undue strain placed upon the abdominal wall and inguinal canal.

It is of interest to note that 9 inguinal herniae (all in men) were discovered on routine follow-up examination on the side of the femoral herniotomy, and in every case no history could be obtained of an inguinal hernia having been present before operation. This is of considerable importance, first because patients often, and very naturally, assume that the femoral hernia has recurred—an assumption sometimes shared by their doctor, and secondly because it casts some doubt on the statement that Lotheissen's operation, by interfering with the posterior wall of the inguinal canal, predisposes to the subsequent development of a direct inguinal hernia. In the present series of cases no such interference took place, yet 7.5% when examined exhibited an inguinal hernia. Presumably a certain number must have been present initially and been

## A REVIEW OF FEMORAL HERNIAE

## WITH SPECIAL REFERENCE TO THE RECURRENCE RATE OF THE LOW OPERATION

BY

ANDREW G BUTTERS, FRCSEd

Late Surgical Registrar the Royal Hospital Sheffield

A great deal of attention has recently been centred on the various methods available for the repair of inguinal herniae and the advantages and disadvantages of the Bassini method, figures have been produced to indicate the appropriate recurrence rates of the various operative procedures at present in favour. Comparatively little, however, has been said of femoral herniae, and it was thought to be well worth while reviewing a series of consecutive cases with a view to ascertaining the recurrence rate of the so-called low operation.

In the years 1942 to 1946 inclusive 178 cases of femoral hernia were operated upon in one of the surgical units of the Royal Hospital, Sheffield. 72 were in men and 106 in women, thus giving a ratio of 1 to 1.5—a far higher incidence in men than is usually accepted. There were 45 strangulations, or 25% of the total.

During the same period there were 807 inguinal herniae, 751 occurring in men and 56 in women, with a total of 21 strangulations, or 2.7%, it will thus be seen that in this series inguinal herniae were 4.5 times more common than femoral, and men were affected 13.4 times more often than women. The statement that inguinal herniae are more common in women than femoral is not in accordance with these figures, for there were only 56 inguinal as compared with 106 femoral making the latter almost twice as common. (It should be noted that no children under 6 years of age are included in this survey, as they are admitted to the Children's Hospital.)

Of the 178 femoral cases, 109 were on the right side and 69 on the left, thus there would appear to be a greater tendency to herniation on the right side. (This was also found to be the case with inguinal herniae, the right side being affected more often than the left—438 and 369 respectively.) There were only four bilateral cases, in contradistinction to inguinal herniae where it is undoubtedly much more frequent. The average age was 50 for men and 53 for women and in the whole series the youngest was 8 and the oldest 79. As already mentioned there were 45 strangulations (25%)—13 in men and 32 in women. Thus there is a marked difference between the two sexes

overlooked, the femoral hernia being the presenting finding, whilst others would appear to have developed subsequently it seems reasonable to suppose that a patient who develops one form of hernia is more liable to develop another. From the practical point of view it is of importance to examine carefully the inguinal regions in every case of a femoral hernia before confining the operation to the femoral canal. It is also of importance to examine recurrent femoral herniae carefully before accepting the fact that recurrence has taken place, for in a number of instances the femoral herniorrhaphy will be found to be sound, the so called recurrence being inguinal in nature.

### Causation of Femoral Hernia

It is usually assumed that whereas indirect inguinal herniae are certainly congenital in origin, inasmuch as there is a pre-existing peritoneal sac, femoral, on the other hand, are probably acquired—that is to say, increased abdominal pressure at one time or another pushes out a peritoneal pouch through the patent femoral canal and so the hernia is produced. With regard, however, to the age limits of femoral hernia, the youngest case in this present series being 8 (though recently a strangulated Richter hernia was observed in a child of 3), such cases cannot be regarded as other than congenital in origin. If some are undoubtedly congenital the possibility of all being so has to be seriously considered—a point of view held by Hamilton Russell, who thought that a peritoneal diverticulum was present in the femoral canal by virtue of the developing limb-buds drawing down the peritoneal lining of the abdomen along the course of the femoral artery.

The fact that the result of operative cure is so satisfactory, especially in the elderly, would tend to support the congenital theory, for efficient closure of the crural ring is difficult to achieve, if indeed not impossible, and if the majority of femoral herniae were acquired it would seem likely that the recurrence rate would be greater, as is indeed the case with direct inguinal herniae when compared with indirect. On the other hand, the average age of development of a femoral hernia is 50 or over, and this is more in keeping with the acquired as opposed to the congenital theory, it therefore seems probable that, although some cases are undoubtedly congenital in origin, the majority are acquired. In this way the greater frequency of femoral herniae in the female sex can be accounted for, as the female pelvis is broader than the male and consequently the femoral canal is larger, with a greater tendency to the development of a hernia, though, as already stated, this has been found to be only one and a half times more common in the female.

Whatever the causation of a femoral hernia, be it congenital or acquired, there can be no doubt that operation should be advised in nearly every case, irrespective of age, and the operation strongly recommended is the low herniotomy repair. For some years now the high operation has not been performed, it was considered unnecessary, and the present follow-up figures of just over a 3% recurrence would appear to justify such a course. Other more complicated operative procedures sometimes recommended, such as Henry's abdominal extraperitoneal approach, would appear to have but very limited use.

### Vital Points in the Low Operation

The vital steps in the procedure are undoubtedly the isolation of the neck of the sac at the highest possible level, the cleaning of the sac completely free from all extraperitoneal fat, and the separation of the bladder from

the upper part of the sac. In carrying out these procedures care must be taken on the one hand not to split the peritoneal sac, thus making it difficult to transfix securely, and on the other not to injure the bladder when freeing it from the neck of the sac. The teaching of the low femoral repair is to transfix the sac, the whole sac, and nothing but the sac, and that means no bladder and no extra peritoneal fat.

It is usually assumed that when a diverticulum of the bladder is found on operating for a recurrent femoral hernia the diverticulum is to be blamed for the recurrence, whereas it is more likely to be the opposite—that is to say, at the time of the first operation the sac was transfixed too low down and the bladder left adherent to the neck, with the inevitable result that recurrence took place, the bladder tending to pull down a further pouch of peritoneum, the mechanism being the same as for a sliding hernia.

From the low approach, either through a short vertical incision over the femoral canal or, better, through an incision just below and parallel to the inner half of the inguinal ligament (this gives a considerably nicer scar and an equally good exposure), it has been found that the neck of the sac can readily be cleaned and defined and freed from all surrounding structures with comparative ease, and when ligated and excised retracts well above the inguinal ligament. It cannot be too strongly emphasized or too often repeated how important is the clean dissection of the sac and its isolation to as high a level as possible, and when transfixed and excised the ligated end should disappear through the canal with perfect freedom, if the sac has not been sufficiently well defined this will not readily happen, as it will be found that the ligature has included other structures as well as the peritoneum of the sac, and recurrence is much more likely to take place subsequently.

It is probably sufficient in most instances merely to excise the sac, but it is a simple procedure to suture the inguinal ligament to the pectineus fascia, and it is as well to narrow the canal in this way. It has been found that the method whereby a flap of pectineus fascia is turned up and sutured to the inguinal ligament, thus obstructing the femoral canal, is of little practical use, as the fascia is too thin to be of much value and the canal is closed at its exit rather than at its entrance.

The criticisms sometimes levelled at the low operation, that the sac cannot be ligated high enough and that the femoral canal cannot be adequately closed from below, have not been found to be valid. The recurrence rate of this procedure has been stated to be as high as 20-30%, but the present series disproves such a statement, which, to say the least of it, is misleading to the inexperienced surgeon and tempts him to embark on one of the more complicated operative procedures, sometimes with anything but pleasing results.

The low repair is so simple, and can so easily be performed under local analgesia with such gratifying end results and in non-strangulated cases with an almost negligible mortality (there were no deaths in the present series), that it would seem to be making surgery needlessly difficult to perform femoral herniotomy in any other way except under very special circumstances.

### Comment

In the present series all the strangulated cases were operated on in this manner and no undue difficulties were encountered. The risk of injury to an abnormal obturator artery when operating from the low approach would appear to be very small, and in a far greater number of cases than are at present under review no such injury has occurred.

In cases requiring a resection for gangrenous bowel it has been found to be more satisfactory to open the abdomen through a separate paramedian incision rather than attempt resection from below, and the various methods whereby more room is obtained, such as division of the inguinal ligament, are not to be recommended. In the vast majority of cases resection is not required, and the operation can be most successfully completed from the low approach only.

### Summary

A series of 120 cases of femoral hernia treated by the low operation have been carefully examined and the recurrence rate found to be 3.3%.

There was no recurrence in the 54 male cases. Heavy work, chronic cough, and the presence of strangulation did not especially predispose to recurrence. Of this series, six cases had previously been operated upon, one of these has since recurred, the other five have remained sound up to date.

Recurrence may take place at any time after operation—in the present investigation from three months to seventeen years—though it is much more likely to recur within the first year.

The clean dissection of the neck of the sac and its high transfixion are of prime importance, and only the sac itself must be included in the ligature. This clean dissection can be adequately performed from the low approach.

The low operation is suitable for almost every case, and gives most satisfactory results.

Even though the inguinal canal was not disturbed, 7% subsequently developed an inguinal hernia on the same side as the previous femoral repair.

Operation should be advised for nearly all cases of femoral hernia, as the results are so good and the low repair is so simple. Remarkably few patients are considered unfit for herniotomy, and the ever present danger of strangulation is an indication for treating all cases by this surgical procedure.

The high incidence of a Richter hernia is to be noted.

Figures sometimes given stating that the low operation has a high recurrence rate would seem to be quite misleading.

The relationship of inguinal to femoral hernia has been found to differ in some respects from the accepted teaching, notably in the finding that femoral herniae are twice as common as inguinal in women, and that femoral herniae occur only one and a half times as often in women as in men.

In inguinal hernia the percentage of strangulations was only 2.6 whilst in femoral hernia the figure was as high as 25%. The presence of a femoral hernia is therefore potentially almost ten times as dangerous as an inguinal, and whilst a truss is sometimes advisable for the latter it is highly doubtful if it should ever be advised for the former.

I wish to thank Mr. H. Blacow Yates, senior surgeon, the Royal Hospital Unit, Sheffield, under whose care all these cases have been admitted, for his criticism and help in preparation of this paper.

The first of the series of regional courses in health education which the Central Council for Health Education is providing for various professional groups in university centres throughout the country was held in Birmingham on Sept. 13 and 14 for public health nurses, of whom 117 attended as the nominees of 12 local authorities in Hereford, Leicestershire, Shropshire, Stafford, Warwick, and Worcestershire. The course was held in the extra mural department of Birmingham University, and the six lectures were given by Dr. R. G. Record, Lecturer in Social Medicine ('Personal and Environmental Factors Affecting Health'), Dr. Jean Mackintosh, Reader in Paediatrics and Child Health ('Physical Care of the Child—the Modern Outlook and Problems of Childhood'), Mr. E. C. Cull, B.Sc., Lecturer in Education and Psychology ('Learning and Teaching') of the staff of Birmingham University, Miss M. Slack, S.R.N., S.C.M., Tutor to the Health Visitors' Training Course, City of Birmingham ('Psychological Needs of the Child'), and Dr. Norman Parfit, Deputy Medical Adviser, the Central Council for Health Education ('Health Education—the Nurses' Part'). Dr. H. P. Newsholme, medical officer of health for the City of Birmingham, took the chair at the opening lecture. A similar course for sanitary inspectors in this area will be held in Birmingham on Nov. 15 and 16.

## REPAIR OF FEMORAL HERNIA BY A "POSTAGE STAMP" FASCIAL GRAFT

BY

H. A. KIDD, FRCS, MRCOG

Senior Surgeon, St. Helier County Hospital, Carshalton, Surrey

The closure of the femoral canal presents a problem which has not yet been solved by the adoption of a standard technique, although numerous methods have been described and have their adherents. As the proportion of femoral to inguinal herniae is about 1 to 15 it is not easy for any individual surgeon to collect a large series and allow an adequate time to elapse before assessing the final results.

The method here described was first performed by me in May, 1938, and has since been employed in 53 cases (51 patients). The principle of the operation is to cut a rectangular section of external oblique aponeurosis, leaving the attachment to Poupart's ligament intact, and then swing it down so that the free margin can be sutured to the periosteum of the pubic ramus. The femoral canal is thus closed by a trap-door of living fascia. The operation can be performed under a regional block with 1% procaine solution, but a spinal or general anaesthetic is preferable.

### Technique

1 The incision extends from the midline, outwards for 4 in (10 cm), parallel to Poupart's ligament and 1 in (2.5 cm) above this structure. It is carried down to the external oblique aponeurosis.

2 Haemostasis is secured and "tetra" cloths are clipped into position.

3 Poupart's ligament is defined and a 3-in (7.5-cm) incision made through the external oblique aponeurosis a full inch above the upper border of the ligament.

4 In the male the cord is retracted. The fibres of the conjoint tendon are then divided transversely for 1 in at the level of the femoral canal.

5 The neck of the sac is defined, the peritoneum opened, the sac dissected out and amputated at its neck.

6 The neck of the sac is closed with fine proofed silk and the original opening in the peritoneum closed.

7 The upper edge of the wound is retracted by a Czerny retractor deeply placed and the lower edge pulled down by two Spencer Wells forceps applied to the lower cut edge of the external oblique. The upper end of the femoral canal is then clearly defined, the coverings of the sac are ligated and usually left in situ so as to fill up the canal.

8 A flap as illustrated, is cut from the lower edge of the external oblique after delineating the points of section with Spencer Wells forceps. It should be a little over 1 in square according to the size of the femoral canal.

9 The femoral vein is retracted laterally with the forefinger. A very small fully curved steel needle on a holder is made to take a good bite of the periosteum of the pubis at the point where the internal border of the femoral vein lay before it was retracted. The fine proofed silk sutures are then threaded twice through the free edge of the graft (as in inserting a pin). The double bite prevents the tissue tearing, and a knot is tied in the ligature at this point.

10 Two similar sutures are passed and fixed, one in the middle of the canal and graft and the other at the internal end.

## Medical Memoranda

### Herniorrhaphy Plus Appendicectomy

It is generally agreed that it is a wise procedure to perform incidental appendicectomy during any abdominal operation provided that the condition of the patient is satisfactory and that no undue prolongation of the incision is called for.

Thus, following a cholecystectomy for gall stones it is usually an easy matter to withdraw the caecum and perform appendicectomy, provided that there are no adhesions in the ileocaecal region. Even so, it may be possible to separate frail adhesions digitally. Firmer adhesions commonly indicate previous appendicular inflammation, which increases the desirability of removing the appendix. In such cases extension of the incision is usually justifiable in order to gain access to the pathological organ.

The majority of gynaecologists scrutinize the appendix after a pelvic operation and if the condition of the patient is satisfactory, perform appendicectomy. The recognized exception to this routine is the presence of raw surfaces or tissue planes such as may result from removal of a tubo-ovarian abscess or a total hysterectomy. In such cases most gynaecologists consider that the release of a few organisms might result in an inflammatory reaction which would not otherwise have occurred. (The introduction of a few millilitres of "mickraform" sulphathiazole suspension would possibly counteract this risk.)

There is one common surgical operation in which incidental appendicectomy can usually be performed without difficulty, but to the best of my knowledge few surgeons avail themselves of the opportunity. I refer to right inguinal herniorrhaphy. After opening the sac and dealing with the contents, unless the neck is unduly narrow, it is often a simple matter to withdraw the caecum and then to remove the appendix. The caecum normally lies just above the internal abdominal ring, and gentle traction with dissecting forceps the serrations of which are covered with rubber tubing usually coaxes the caecum into the sac. If the caecum does not present itself, or is immobilized by adhesions the manoeuvre must be abandoned, but in more than half of the cases appendicectomy by this route presents no difficulty. Patients who undergo radical repair of a hernia are usually fit enough to withstand a short prolongation of the operation, and they are invariably surprised and delighted to learn subsequently that they have been relieved of an organ which possesses no virtue but only potentialities for mischief.

One very important point when a patient has undergone incidental appendicectomy it is the duty of the surgeon, the assistant, and the sister in charge to inform him and a responsible relative that the appendix has been removed. Any surgeon of experience will recall patients with abdominal scars who are entirely vague about whether they possess an appendix or not. The complacency with which some patients offer their abdomens as a sacrifice to the surgeon's scalpel is a remarkable tribute of confidence, and they are quite content to wander forth again into the world in complete ignorance of the reason for or the results of surgical intervention.

R J McNEILL LOVE MS, FRCS

The Northern Ireland Minister of Health and Local Government Mr William Grant, speaking at the annual dinner of the Northern Ireland Branch of the Chartered Institute of Secretaries, said that the number of doctors in the health scheme was 730 while the number of persons on doctors' lists at July 5 was 996 051. This had since increased to approximately 1,250 000 representing 93% of the total population. New acceptance cards were still being received at a steady rate, and the response had been gratifying. The payment now being made to doctors out of the Practitioners' Fund (calculated at the rate of 17s 6d a year in respect of 95% of the total population) was £266 627. Payments to dispensing doctors for drug capitation fees totalled £12 481. These were the gross figures before deduction of superannuation contributions.

11 When the proximal ends of the ligatures are pulled upon the flap rolls down like a blind to cover the femoral canal opening. The graft is fixed by tying the sutures and tested by the finger to see if a good fit has been obtained with the right degree of tension.

12 The cut edge of the conjoint tendon is then sutured to Poupart's ligament with interrupted silk sutures.

13 The external oblique is closed with interrupted silk sutures. A little ingenuity may be required to close the gap made by the removal of the graft, but it can usually be managed without undue tension or the performance of the relief incision parallel to and above the original cut in the external oblique.

14 The skin is closed with interrupted silkworm sutures.

Patients are taught to do special exercises both before and after operation, and the stitches are removed on the tenth day. They sit out of bed on the second day, walk about on the twelfth day, and go home on the seventeenth day. Light work is allowed four to six weeks after operation and heavy lifting only after a further three months.

The chief danger in the operation is of damage to the femoral vein when passing the first deep suture. The use of a small, strong, trocar-pointed  $\frac{1}{2}$ -in (1.25-cm) needle is essential. The disadvantages in the operation are the small transverse incision in the conjoint tendon and the gap left in the external oblique, as both may tend to the formation of a direct inguinal hernia. It is important to close the opening in the posterior wall of the canal by carefully placed interrupted silk sutures to prevent a direct inguinal hernia.

### Results

There were two recurrences of the femoral hernia, both in men one of which was an emergency operation for strangulation in a man aged 63.

Four patients died—only one in hospital, a few days after an operation for strangulated hernia in a patient of 78. One patient died two years after operation, and her doctor states that there was no recurrence. The third died eight months after operation from a carcinoma of the lung, and when seen two months before death there was no recurrence. The fourth died at home suddenly, aged 67, cause unknown, a few days after discharge.

Table of Results

	Male	Female	Totals
Incidence			
Right	12	25	37
Left	4	12	16
Strangulated			53
Right	8	7	15
Left	2	2	4
Bilateral	—	2	2
Recurrent			
Femoral	1 (s)	1	2
Direct	1	1	2
Died	2	2	4
(Age at death)	(67 67)	(78 84)	

Age —Average over 50, oldest 84, youngest 24. Sex —Males to females 1:2. Side —Right to left 2:1. Strangulation —2:5. Pain in scar —3 (1 male 2 females). Follow up —Longest 10 years, shortest 1½ years (February) on since January 1947.

### Summary

An operation for femoral hernia has been described in which the canal is closed by a "postage stamp" graft of living fascia.

Since 1938 53 operations on 51 patients have been performed and have been followed up for 1½ to 10 years. Only one patient could not be traced.

There were two recurrences of the femoral hernia and two direct inguinal hernia.

## Reviews

### THE YOUNG CHILD'S PERSONALITY

*The Personality of the Preschool Child The Child's Search for His Self* By Professor Werner Wolff (Pp 341, 118 figures 25s) London William Heinemann Medical Books 1947

Intelligence tests are not altogether holding their own. Clinicians trust the results of routine tests on children only in so far as they are carried out by mature and understanding psychologists who make a good guess intuitively after adequate human contact. Tests of children under six are particularly suspected, and perhaps ought to be thought of as research. This study of the pre-school child is very interesting, is in many respects original and is successful in getting behind the objections to the testing with which we are more familiar. The author's aim is to study the child and not to churn out quotients. He discusses the "rhythm quotient," which serves to introduce organized comment on and evaluation of the drawings of children who have not learnt to draw and who draw subjectively rather than objectively. The book is profusely illustrated by children's conversations and drawings, and these ensure that the reader is kept in touch with the child that is being studied and is not lost in theory. The reader is free to see more than the author sees or to disagree with the author's drawings and comments.

The psycho-analyst, who concerns himself specifically with the dynamic aspect, who sees a need in therapeutics for resolving the repressed unconscious, will welcome this alternative non therapeutic approach which enriches his perception of the young child's way of life and natural organization. For the educational psychologist the work described in this book would seem to offer a most welcome opening out of the subject and an escape from the psychologist's dilemma—his being employed more for his comments on cases based on guesswork, than for actual results of tests performed. No doubt much that is published by Wolff as original is a development of ideas already suggested by other workers, but if this is so the author is exonerated by his providing an extensive bibliography of 622 relevant books and papers.

D W WINNICOTT

### V D HANDBOOK

*Handbook of Venereal Infections* By R. Grenville Mathers, M.A., M.D., FRFPG, Ph.D., A.R.I.C. (Pp 116 12s 6d) London Sylvio Publications, Ltd. 1948

The author of this little book has been remarkably successful in getting so much information, in fact nearly all that practitioners and senior students require, into fewer than 110 pages. In the opening chapter he considers the legal aspects of the subject, including Regulation 33B (which has now been revoked), and the facilities for free treatment provided all over the country. Chapter II is on penicillin and its use in venereal diseases. Then follow chapters on gonorrhoea, syphilis, and other venereal infections, with a final one on the prevention of V.D. His account of gonorrhoea occupies 27 pages, and he discusses diagnosis and treatment on standard lines. There are 60 pages on syphilis, and they include a good description of the technique of dark-ground microscopy. A fuller account of the morphology of *Spirochaeta pallida* would have been helpful. He describes the Wassermann reaction at some length, but it seems doubtful whether the neophyte would fully grasp its meaning. The description of the various stages of syphilis and the treatment recommended are sound, and the author evidently is not one of those who pin their faith on penicillin alone, very wisely he insists that this must be supplemented by other remedies if the maximum effect of therapy is to be obtained.

Unfortunately the generally low standard of scholarship and the numerous mistakes, typographical and otherwise, somewhat mar this little book. The author evidently has not profited from his study of the *litterae humaniores* at school and the university, such words and expressions as "spirochaetocidal" "flagellae" "grains 1/12" "0.2 mega units," "practice" (substantive) and "one month's rest between each course" should not occur, while singular nouns appear with

plural verbs and vice versa with gay abandon. It is news to most that in meningo vascular syphilis the meningitic gold curve is 00001344300 and that interstitial keratitis is a lesion of the nervous system. If the author will carefully study Sir Ernest Gowers's *Plain Words* and occasionally refer to Fowler's *Modern English Usage* the second edition of this book will be a great improvement on the first.

T E OSMOND

### ENDOTRACHEAL ANAESTHESIA

*Endotracheal Anaesthesia* By Noel A. Gillespie, D.M., B.Ch., M.A., D.A. Second edition, revised and enlarged (Pp 237, 56 figures \$4.00) Wisconsin University of Wisconsin Press 1948

Like so many other arts of the cunning hand, endotracheal intubation can be learnt only by practice. The way of the self-taught intubator is hard and blood-bespattered. An enthusiastic and experienced teacher at his elbow makes difficulties disappear and understanding come easily. When this stage is reached a good book waters the newly flowering skill with knowledge and the erstwhile novice soon becomes an expert. Such a book was the first monograph on endotracheal anaesthesia by Professor Gillespie. The first edition in 1941 seemed impossible to improve, but he has succeeded in doing so by including an account of the latest developments in the technique. There can be little that has been said or written about endotracheal anaesthesia that he does not discuss. Nevertheless, the vast array of fact, historical and recent, practical and theoretical, is put concisely, yet with such excellent style and with emphasis so well placed that one reads the book with no feeling that the subject matter is compressed. The bibliography and references are painstakingly set out at the end of each chapter.

Professor Gillespie is fair when discussing such poor methods and dangerous practices as have inevitably sprung up, but in moderate and scholarly language he manages gently though effectively to shape the reader's opinion to his own. Not only the anaesthetist but his colleagues too will find this book interesting, for the author describes well the great inventiveness, ingenuity, and effort that attend the apparently simple manoeuvre of passing an endotracheal tube and administering an anaesthetic through it. The author is a product of both the London Hospital and of the Madison School of Anaesthesia. This excellent work must be a source of pride to both.

WILLIAM W MUSHIN

### HYPNOTISM

*Hypnotism To day* By Leshe M. Lecron, B.A., and Jean Bordeaux M.A., Ph.D. Foreword by Milton H. Erickson, M.D. (Pp 278 25s) London William Heinemann Medical Books 1947

In the first half of this book the authors give an interesting account of the history of hypnotism and a description of the physiological and psychological phenomena and the theories which have been suggested to explain them. The phenomena are themselves remarkable. There can be no doubt of the reality of the anaesthesia which can be produced. The normal subject can tolerate, though with pain, 15-20 volts, while the hypnotized subject under the same conditions has taken without flinching 120 volts. Major operations have been conducted under hypnotic anaesthesia. This is intelligible on present neurophysiological conceptions, but it is a different matter with hyperaesthesia, about which, to be sure, the evidence is not quite so convincing. Playing-cards with presumably identical backs are shown face down to the hypnotized subject, but each is described as a photograph—for example, of a landscape or portrait. The cards are then shuffled and again shown face down. It is said the subject can identify the cards by the suggested pictures which have been associated with each of them. Some of the subjects who have succeeded with this test have been able to point to minute differences between the cards which, under suggestion, became a feature of the hallucinatory picture. Another improbable phenomenon is that of regression. By appropriate suggestion the subject can be brought to retreat to any age of his life—for instance, early childhood—and then takes on the behaviour, abilities, and vocabulary of that age and can remember precisely and in detail as recent events occurrences of that remote past. Such observations

suggest strongly the desirability of further research in this obscure field

In the second part of the book the authors give useful indications for the treatment by hypnosis of neurotic states. They write in an interesting and informative way and in a critical and cautious spirit emphasizing the need for adequate medical investigation before hypnotic treatment is started.

ELIOT SLATER

## SCIENCE AND SOCIETY

*The Conflict of Science and Society* By C D Darlington FRS Conway Memorial Lecture at Conway Hall April 20 1948 (Pp 51 2s) London Watts and Co

The publishers of Dr C D Darlington's Conway Memorial Lecture justly describe it as provocative. From its denunciation of Government departments in our bourgeois State particularly of the Ministries of Agriculture and Health and its more than Wellsian contempt for our ancient universities a young Marxian might think he recognized a comrade, but, as our readers will remember, Dr Darlington has an even poorer opinion of the USSR than of the Ministry of Agriculture which has not, apparently, murdered anybody yet while Moscow has murdered several geneticists and compelled the Academy of Sciences of Prague to offer a seat to a charlatan from Moscow. The evils of the world are Dr Darlington thinks to be traced to the notion of equality, one of the three chief illusions promoted by the great Semitic religions (which are the Christian, the Muslim, and the Communist faiths). Christian or Muslim equality depends on an equality of souls before God. Germanic equality depended on an equally mystical race-theory. Marxist equality, on the other hand, springs from a variety of sources. Is it possible that Dr Darlington is misstating the Christian ethic? The parable of the talents seems to teach that all men are *not*—shall we say—*genetically* equal, but that there is equality of reward between the possessors of five talents and of two talents provided they have used their greater or smaller genetic abilities as well as they could. However this may be Dr Darlington finds the world very evil and that organized society has no use for research. 'Is our situation so easy, our food so abundant, our empire so rich, our credit so inexhaustible, that we can afford the perennial and increasing archaism of our great departments of Industry, Agriculture, and Health?'

Dr Darlington's remedies for this state of affairs are far from violent. He thinks that nobody should be given a university degree from whose training either science or the humanities has been wholly excluded and that the theory of evolution should become the central idea in teaching and research. These proposals will be found *mutatis mutandis* (viz., without a drum fire of scorn) in the report of the BMA Committee on Education.

The heart knoweth its own bitterness, Dr Darlington's emotion is perhaps stirred by British neglect of genetics, which indeed moved the wrath of Karl Pearson and Galton before Dr Darlington was born. It would be impertinent for a vital statistician without special knowledge of genetics to challenge Dr Darlington's judgment on that issue, but I shall venture to deny as categorically as he affirms that the official vital statistics of this country are 'largely lumber' or that modern statistical methods are despised in Government departments. Indeed the demand for trained statisticians both in Government departments and universities is considerably greater than the supply.

MAJOR GREENWOOD

Professor J H Burn FRS, says in his *Lecture Notes on Pharmacology* (Oxford Blackwell Scientific Publications, 6s) 'These notes were written for the medical students at Oxford because very few of them were able to obtain copies of textbooks on pharmacology.' He gives a concise account of the information needed to pass examinations and this will help students to achieve the necessary goal. The danger of this kind of book lies in the fact that some students may feel that there is no need to consult larger books and so will require a minimum of knowledge. The book is reliable, up to date and well suited for its purpose, but it will be unfortunate if students have to depend entirely on such brief summaries. If the appearance of this book stimulates the publishers of larger textbooks to print more copies of them a useful purpose will have been served.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Practical Zoological Illustrations Invertebrates* By W S Bullough (30 illustrations 15s) London Macmillan 1948  
Labelled diagrams for junior students of zoology

*The Modern Management of Gastric and Duodenal Ulcer* Edited by F Crodon Deller M D, M R C P (Pp 221 20s) Edinburgh E and S Livingstone 1948

A practical account for physicians and surgeons

*The March of C M E* Edited by L Machlan for the College of Medical Evangelists Vol II (Pp 208 No price) California College of Medical Evangelists Loma Linda and Los Angeles 1947  
An account of the College of Medical Evangelists, California

*Pharmacology and Experimental Therapeutics* By H A Anderson and others (Pp 368 36s) London Cambridge University Press 1947

A survey of the literature, 1941-6

*Medical Statistics from Grant to Farr* By Major Greenwood D Sc F R C P, F R S (Pp 73 6s) London Cambridge University Press 1948

The FitzPatrick Lectures for 1941 and 1943 an account of the early history of medical and social statistics

*Zinsser's Textbook of Bacteriology* By D T Smith, M D, and others 9th ed (Pp 992 \$10) New York Appleton Century Crofts 1948

For medical students and practitioners

*The Selection and Use of Diagnostic Categories in Clinical Counseling* By H B Pepinsky (Pp 140 11s 6d) London Geoffrey Cumberlege 1948

A monograph on identifying and advising on students' problems

*Father Land* By B Schaffner, M D (Pp 203 18s) New York Columbia University Press 1948

A study of authoritarianism in the German family

*A Synopsis of Regional Anatomy* By T B Johnston, C B E M D 6th ed (Pp 436 18s) London J and A Churchill 1948

For the medical student revising his work

*General Endocrinology* By C Donnell Turner, Ph D (Pp 604 35s) London W B Saunders 1948

A textbook for students of biology and zoology

*Malaria Control by Coastal Swamp Drainage in West Africa* By A B Gilroy, O B E, M B, B S, D T M & H (Pp 107 No price) London Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine 1948

A practical handbook intended primarily for medical men

*Human Ancestry* By R Ruggles Gates, F R S (Pp 422 42s) London Geoffrey Cumberlege 1948

A study of the origin and history of the races of mankind

*Insects and Human Welfare* By C T Brues Revised ed (Pp 154 14s) London Geoffrey Cumberlege 1947

An account of insects harmful to man and their control

*Fearless Childbirth* By M Randall, O B E, S R N, S C M, M C S P (Pp 99 3s 6d) London J and A Churchill 1948

A practical handbook for the mother to be

*The Mechanism of Abdominal Pain* By V J Kinnella, M B, Ch M, F R C S, F R A C S (Pp 230 32s 6d) Sydney Angus and Robertson 1948

Includes a historical introduction and review of the literature, with references

*Brief Psychotherapy* By B S Frohman, M D (Pp 265 20s) London Henry Kimpton 1948

A manual for the general physician

## PROTEIN IN FOOD

Many will remember being taught that different proteins contain different combinations of amino-acids and that in all animals a process of selection goes on, the correct proportions of the amino-acids needed for the building up of their own characteristic proteins being sorted out and any which are left over used merely as fuel. Some of us may also have been told that cannibalism is justifiable at least on physiological grounds, because the proteins thus consumed supply amino-acids in the right proportions. While some of these conceptions have stood up well to the test of time, much has been learned in recent years about protein metabolism and about the body's need for protein. Elsewhere in this issue we publish the paper on the significance of proteins in nutrition which Dr D P Cuthbertson read when opening a discussion in the Section of Nutrition at the Annual Meeting of the British Medical Association.

The old division of proteins into two qualities has now become much less justifiable. It is still true that proteins of animal origin, with the main exception of gelatin, contain all the necessary amino-acids in the right proportions, whereas in vegetable proteins certain essential amino-acids are absent or present in inadequate amounts. The food we eat, however, contains many different proteins, and lack of certain amino-acids in one may be made good by their abundance in another. Thus, while beef tea is deficient in tryptophan and tyrosine and bread in lysine, the long-popular combination of the two provides amino-acids in reasonably well-adjusted proportions.<sup>1</sup> The time factor is important when one protein has to make good the deficiencies of another. Cannon<sup>2</sup> has pointed out that an "all-or-none" law applies to the synthesis of protein in the body. Each tissue protein is always built up accurately to its characteristic structure, if any essential amino-acids are missing partial synthesis of body protein cannot take place, nor can surplus acids be stored until the missing ones are provided. Even a period of a few hours between the ingestion of different proteins may be too long if they are needed to supplement each other. We must have bread and beef tea together, not bread in the morning and beef tea in the afternoon.

Cuthbertson's conclusions about the quantity of protein which the diet should contain support the theory that if a diet is adequate in calories it will usually be adequate in proteins as well. Thus American soldiers chose diets containing 11-13% of protein irrespective of the part of the world in which they were serving. The oedema which was a sign of protein deficiency in prisoners in European and Asiatic prison camps during the war was mainly due to the demands of the body for dietary and tissue proteins as

sources of energy. Adults can quite well do without animal protein, but when poverty does not restrict choice of food it is usual to find that 60% of the total intake of protein is in this form. Unless children are given a substantial proportion of animal protein in their diet they may not obtain enough lysine for their needs.

Wounds, accidental injuries, and burns may cause the loss of proteins not only in visible forms, such as detached or broken tissues and bleeding and exudation from the damaged area, but also through the excessive protein catabolism which normally follows injury, through superimposed infection, and through disuse or reflex atrophy resulting from the immobilization of the patient during recovery. As an illustration of the severity of the protein loss after severe injury Cuthbertson mentions that a patient lost 8% of his total body protein within ten days after breaking a leg. While this heavy loss of protein may seem alarming, the process appears to be part of the normal mechanism of repair and provides the amino-acids required to build new tissues. When the protein reserves of experimental animals are exhausted no increase in protein catabolism takes place after injury, this implies that the normal powers of recovery are impaired. Severely injured patients should certainly be given a diet which will restore a positive protein balance without undue delay. For this purpose it is not enough to give protein in amounts equal to those lost, unless sufficient carbohydrates and fats are provided to meet the total need for calories the protein is merely used as fuel. Undernourished patients who are awaiting operation should be put on diets which will meet their nutritional needs, since they may respond to dietary treatment more readily before operation than during convalescence.

Cuthbertson also describes the somewhat similar problems of protein balance during the treatment of fevers, which resemble starvation in causing destruction of the tissue protein. In acute febrile illnesses it is more important that the patient should be saved exertion than that his protein intake should be increased. In fevers of long duration, however, liberal amounts of milk and of carbohydrates should be given. Protein hydrolysates, of which so much was once expected, do not now seem to have a wide application in the treatment of either injuries or disease. When the patient is able to digest intact protein the administration of hydrolysates is physiologically unjustified, while if nourishment has to be given intravenously plasma and glucose usually provide a safer alternative.

## MULTIPLE MYELOMATA

In the *Philosophical Transactions* of the Royal Society of London for 1848 there appeared a short article by Dr Henry Bence Jones in which he described the properties of a substance found deposited in the urine of a patient suffering from mollities ossium. The peculiar characteristic of this substance was that it dissolved in boiling water, and the precipitate formed on the addition of nitric acid was dissolved by heat but reformed on cooling. Knowledge of the condition now known as multiple myelomatosis has grown from this observation. The disease is not rare, but it is often missed. It is more

<sup>1</sup> *Cham. H. Brit. Med. Journal* 1948 2, 103

<sup>2</sup> *J. Amer. med. Ass.* 1947 135 10-3 and *Proc. Inst. Med. Chicago* 1948 17 1

common in males and usually affects those in the fifth and sixth decades. The average time after the onset of symptoms before the patient reaches a hospital is about nine months. The disease primarily affects the marrow of flat bones—the vertebrae, ribs, skull, and pelvis—but occasionally the long bones may be affected, particularly the femur and humerus. The soft tumour tissue may burst through the bone and invade the adjoining tissues, more rarely the liver, spleen, and lymph-glands may be affected, and still more rarely other soft parts. The chief symptoms complained of by the patient are either pain in the back, great loss of weight, or an obvious swelling in a bone, and on examination a pathological fracture may be found, quite commonly a compression fracture of a vertebra. Radiographs often show characteristic rarefaction of one or more bones. In half the cases there is an excess of calcium in the blood, while in a similar proportion (but not the same group of cases) the globulin in the blood is considerably raised. Severe anaemia is common. Material obtained by sternal puncture may contain cells of a type similar to those in the tumour. The urine in about half the cases contains the protein known by the name of Bence Jones and possessing the properties he described, the finding of this is almost but not quite pathognomonic. There is sometimes an atypical nephritis with persistent albuminuria or even renal insufficiency. When sections of the tumour are examined microscopically usually one of two types of cell is seen to predominate—a small cell which has a superficial resemblance to a plasma cell, and a larger cell with more abundant cytoplasm and large round nucleus. According to Lichtenstein and Jaffe<sup>1</sup> cases of large-cell myeloma are characterized by hyperglobulinaemia. There is considerable difference of opinion about how these cells originate, but these authors state that there can be little doubt that multiple myelomatosis “is a disease of unitary cell type, the varieties in cytologic appearance reflecting stages in the maturation of the basic tumour cell”. An interesting point is that at necropsy some cases are found to have amyloid deposits in tissues which are not generally affected in true amyloid disease.

Prognosis in this disease is not good, but remissions sometimes occur. Patients have been known to survive for ten years, but the average duration of life is only about two years from the time when symptoms are first noticed. Treatment by x rays is palliative only. Radioactive phosphorus ( $P^{32}$ ) has been tried by several observers, but with little success. Hall and Watkins,<sup>2</sup> however, apparently cured one patient by a series of injections of radioactive phosphorus followed by x-ray treatment. Because excess of globulin in the blood is a feature of kala-azar, which is cured by administration of antimony, Snapper<sup>3</sup> tried the effect of “sulbamidine” in multiple myelomatosis, pain diminished, and radiographs showed what appeared to be some arrest of the disease and recalcification, but in other ways there was no benefit. Edith Paterson<sup>4</sup> and her colleagues have reported that urethane, which had been found useful in the treatment of leukaemia, produced no improvement in two cases of multiple myelomatosis. Lately, how-

ever, in Sweden Alwall<sup>5</sup> used this drug with success in one out of two cases. The patient was a woman aged 50, with radiographic and other evidence of multiple myelomatosis. Urethane was given in the following doses, first month, 1 g 2-4 times daily, then two weeks' interval followed by 1 g thrice daily for two months, after that 2.5-1.5 g per week. Though improvement was not apparent radiologically the amount of globulin in the blood became normal, the sedimentation rate fell rapidly, and at the end of four months the material obtained by sternal puncture no longer contained myeloma cells. It appears that urethane deserves further trial in this condition.

### FEMORAL HERNIA

Most surgeons of experience in this country practise the high operation for repair of femoral hernia, and there are few who would not use this approach in cases with strangulation. Elsewhere in this issue (p 743) Mr A G Butters reviews the results in a series of 120 cases and puts forward a plea for wider use of the low operation. Numerous American surgeons<sup>1-4</sup> regard the low approach as adequate and the operation of choice in the majority of cases. Wakeley<sup>5</sup> in this country has also given strong support to this view and reported a lower recurrence rate in the patients operated on by him. It is a common criticism of the low operation that complete removal of the sac is not always achieved. Repair of the femoral canal from above would seem to be more certain and effective, but Moschcowitz,<sup>6</sup> who was one of the first to recommend this approach, pointed out that the posterior wall of the inguinal canal might be weakened, surgeons who perform the modern high operation are therefore careful to reinforce the posterior wall of the inguinal canal after repair of the femoral region. Butters reports that even with the low approach 7% of his patients subsequently developed an inguinal hernia on the same side. It would be interesting to know what proportion of these were direct herniae, for they at least should be prevented by a properly executed high operation.

Many methods of closing the femoral canal have been used in the last 50 years. The low operation with simple apposition of inguinal ligament to pectineal fascia may be sufficient where the hernia is small and the femoral canal narrow. The inexperienced surgeon finds it easy, but it is doubtful whether the inexperienced surgeon should undertake such operations, and simplicity cannot wholly justify a procedure which may be otherwise unsound. With the inguinal approach the method of repair used by Keynes,<sup>7</sup> a modification of Bloodgood's<sup>8</sup> operation for inguinal hernia, has given excellent results in skilled hands. On another page Mr H A Kidd describes a method in which a flap of external oblique aponeurosis is used. This operation may have the virtue of avoiding the potential actual defect which occurs at the lateral edge of the rectus in the Keynes operation, but it leaves instead a defect (probably of little importance) in the external oblique. Though there is much to be said for using the patient's own tissues the insertion of a lattice of some unabsorbable suture material has grown in popularity. Interrupted sutures of linen or silk are commonly used, tension being avoided.

In this *Journal* recently Mr A Lawrence Abel and Mr A H Hunt<sup>9</sup> have advocated a continuous lattice darn with fine stainless steel wire. Many surgeons, recalling that stainless steel pins and wires sometimes disintegrate, may be chary of putting wire close to the femoral vein, and time alone will show if this is sound practice.

It is very hard to justify a low approach in cases of strangulated femoral herniae, Butters suggests a separate paramedian incision if resection of gut is necessary, but this may seem irrational to surgeons who prefer the high operation. The low approach may give a totally inadequate view of the strangulated viscus, and cases have occurred where the damaged gut at the edge of an incompletely inspected strangulated Richter hernia has subsequently perforated into the peritoneal cavity. Adequate exposure is vitally important, and though good results are obtained with inguinal or vertical incisions many surgeons favour a paramedian incision, while some find that the pararectal approach devised by Vaughan Hudson gives the best view. Henry's<sup>10</sup> operation is useful for uncomplicated bilateral hernia in suitable patients, but in cases of strangulated hernia the exposure may be inadequate. When a midline incision is used it would seem wise to repair the linea alba with stainless steel wire.

### REGIONAL ORTHOPAEDICS

Thanks to the pioneer work of the late Dame Agnes Hunt and Sir Robert Jones some parts of England have had regional orthopaedic services for about a quarter of a century. The service based on Oxford is a model for the whole country, and a recent pamphlet<sup>1</sup> by one of its past directors, Mr G R Girdlestone, should interest not only orthopaedic surgeons but all who think that the benefits of medicine should be taken to the patient rather than that he should be compelled to drag himself over a greater or lesser distance to a central hospital. A number of orthopaedic surgeons have worked hard to make more widely known the preventive aspect of orthopaedics, and among these Girdlestone has shown very convincingly that in order to make preventive work effective a regional system of clinics is essential. He describes the admirable Oxford service much as it is to-day, with the recent extension of its activities to embrace the treatment of accidents. An accident service, because of its faster tempo, requires something more than a mere expansion of an existing orthopaedic service. Much of the work must be decentralized, surgeons should be installed in the smaller centres of population so that they may deal expeditiously with all accidents occurring in the neighbourhood—the function of the central hospital being to co-ordinate their activities and to provide facilities for the investigation and treatment of the exceptionally difficult or rare case.

Girdlestone's description of a regional orthopaedic service is more likely to be of value to members of regional hospital boards and other laymen interested in the care of cripples than to professional hospital administrators, who will require detailed information on a number of points not dealt with in his pamphlet. For instance, he does not state the number of beds needed per thousand of population, and he gives no information about the size of staff required in relation to the distances to be covered in visiting clinics. The activities of the after-care sisters and the method of arranging their work are not described, nor does he give any indication of the size of the appliance workshops in relation to the population served. There is no mention of

some important clinical problems, such as the best way of treating those troublesome and not infrequent cases of combined pulmonary and joint tuberculosis and the special arrangements required in an outbreak of poliomyelitis. It is doubtful whether anyone in the country is in a better position than Mr Girdlestone to supply all this vital information, and it is to be hoped that he will find time to produce a more comprehensive guide for the benefit of professional hospital administrators and orthopaedic surgeons.

Concentrating his attention on a smaller field—out-patient arrangements and accident services—P W Clarkson<sup>2</sup> has produced a most informative report. He shows how the out-patients' casualty department should be used for medical education, and his description of the arrangements at Guy's Hospital is supplemented by accounts of the organizations at the Royal Infirmary, Edinburgh, the Birmingham Accident Hospital, and the Accident Service at Oxford. A similar report to cover the wider field of orthopaedics and the treatment of accidents on a regional basis is what is now required.

### LATENT RHEUMATIC MYOCARDITIS

In children and young adults with rheumatic heart disease congestive heart failure is almost invariably precipitated by a recurrence of the rheumatic infection and an active carditis. On the other hand, it is customary to regard the congestive failure that commonly terminates rheumatic heart disease in the fourth or fifth decades as being mainly the result of long-standing impairment of valvular efficiency and the associated myocardial fibrosis. However, in recent years the view has been gaining ground that even at the later age a reactivation of the rheumatic process may be the underlying cause of the final heart failure. In an attempt to assess the frequency of active carditis in patients dying with rheumatic heart disease Rogers and Robbins<sup>1</sup> studied the findings at 41 post-mortem examinations carried out at the Mallory Institute of Pathology of the Boston City Hospital between 1933 and 1946. In 20 of these, with ages ranging from 2 to 53, the activity of the disease had been recognized during life on clinical grounds. In 14 there was a history of preceding sore throat or other upper respiratory infection, and all but five had had joint pains or an actual polyarthritis. Clinical evidence of pericarditis was present in 13 of the patients, at necropsy old or recent valve lesions were found in this group, in addition to active carditis as shown by the presence of Aschoff bodies.

In a second group comprising 10 cases the activity of the rheumatic process was not suspected during life. The average age of these patients was 23 years older than that of the first group, the ages varying from 12 to 63 years. In only three was there a history of recent upper respiratory infection, and only three had complained of joint pains. Typical clinical signs of pericarditis were found in none. All had congestive failure. At necropsy these patients were found to have the classical lesions of rheumatic heart disease, all showing an active myocarditis, and in two cases there was a recent acute rheumatic endocarditis superimposed upon the old valve lesion. A further seven patients were not recognized during life as having rheumatic heart disease at all. Their ages ranged from 29 to 63, the average being three years older than the last group and 17 years older than the first. Only three of these patients had signs of congestive failure, and in only one was there clinical evidence of valvular lesions. Yet in these cases too the post-mortem examinations revealed changes as characteristic of rheumatic heart disease as in the two

<sup>1</sup> *Practical Orthopaedic Service*. Obtainable from the Central Council for the Care of Cripples.  
<sup>2</sup> *G. R. Girdlestone*, 1948, 62, 202.

preceding groups. In all cases there were Aschoff bodies in the myocardium, and in four there was a recent valvulitis. In a further four patients there were no clinical signs of rheumatism, but two had congestive failure. At necropsy no valvular lesions could be demonstrated, but myocarditis with the histological features of acute rheumatism was found in all four. In the last group the diagnosis of rheumatic infection based entirely on the presence of Aschoff-body-like lesions in the myocardium is open to criticism. The specific nature of these changes when found alone is still a debatable matter. Nevertheless this study clearly shows that acute rheumatic carditis is by no means confined to childhood and early adult life. Even after the age of 40 an active rheumatic carditis can occur as the sole manifestation of acute rheumatism, and cardiac failure at this age may be the result of a recurrence of rheumatism. These observations also fall into line with the well-recognized fact that patients with rheumatic heart disease sometimes survive to 60 or over with no symptoms of heart failure and then succumb to some other disease, presumably because they have escaped further attacks of rheumatic carditis.

### PSYCHOTHERAPY FOR SEXUAL OFFENDERS

The Scottish Advisory Council on the Treatment and Rehabilitation of Offenders has recently issued a report<sup>1</sup> on the treatment by psychotherapy of certain offenders. The subject has been approached broad-mindedly, and the adoption of the recommendations would probably help to prevent crime. It is a pity that the report should be limited to a consideration of psychotherapy, which is a form of treatment applicable to comparatively few disorders, the recommendations could well include other forms of psychiatric treatment. A sexual offence is often only an episode in the course of a person's psychosexual development, and the Advisory Council wisely suggests that it would be advantageous in such cases to obtain psychiatric advice and, if necessary, treatment rather than to institute court proceedings. Such a course is eminently suitable in the case of children and adolescents, and on occasions courts already follow this procedure in both Scotland and England. The Council appreciates the value of combining probation with psychotherapeutic or psychiatric treatment, whether out-patient or residential, and approves the new facilities to be provided under the Criminal Justice Act, 1948. The necessity for the therapists to be competent and experienced is properly emphasized.

Apart from those whose offence is merely episodic there is another group of offenders who are likely to respond to long-term psychotherapy or other medical treatment. The Council considers that there should be inaugurated in Scotland arrangements for treatment similar to those at present available at Wormwood Scrubs Prison in London. These were first provided in 1934, and after a break during the war were gradually extended to include most modern forms of therapy.<sup>2</sup> It is pointed out that a sentence will have to be of sufficient length for the completion of treatment, and mention is made of the sentences of corrective training created by the Criminal Justice Act. Unfortunately offenders eligible for such sentences, those convicted for the third time of serious offences, will be unlikely to respond to psychotherapy, since it has been found that adults whose criminal activities show signs of becoming

chronic are unsuitable subjects.<sup>3</sup> No mention is made in the report of the treatment of short-sentence prisoners by extra-mural psychiatrists so as to avoid discontinuity of treatment on release.

Finally, the report considers the disposal of sexual offenders who are unlikely to benefit by psychiatric treatment. It is suggested that a term of preventive detention should be imposed on the lines provided in the Criminal Justice Act, but that the sentence should be served in a special State institution similar to that in existence at Herstedvester in Denmark. In 1939 East and Hubert<sup>4</sup> proposed the establishment of such an institution, which would have a therapeutic wing for the treatment of selected cases. Though no steps have yet been taken to carry out this proposal, the project is still under consideration.<sup>2</sup> An alternative suggestion is that offenders certified by two psychiatrists as unlikely to respond to treatment might be sentenced to detention in a State mental hospital. The Advisory Council prefers this alternative, but gives no reasons for its preference. It is difficult to see what advantage detention in a State mental hospital would have over detention in the type of special institution proposed by East other than the indeterminate sentence so strongly urged by Continental penologists for dealing with these offenders.

### TETRAETHYLAMMONIUM IN VASCULAR DISORDERS

The place of the tetraethylammonium compounds in the management of vascular disorders is not yet settled, mainly because there have been conflicting reports about their clinical action. On the one hand, Lyons<sup>1</sup> and Collier<sup>2</sup> and their co-workers claim that the drug produces a peripheral vasodilatation equal to that obtained by sympathetic or peripheral nerve block, on the other, De Bakey<sup>3</sup> in the U.S.A. and Boyd and his colleagues<sup>4</sup> in Manchester have observed a very variable response to the intravenous injection of up to 500 mg—the maximum safe dose—of tetraethylammonium bromide. In many cases there was little or no increase in the peripheral blood flow, though in the same cases sympathetic or peripheral nerve block produced a marked increase. It is thus apparent that the tetraethylammonium compounds do not give a reliable indication of the improvement which sympathectomy may bring about, and that they are not likely to prove so effective in the treatment of vascular disturbances as are repeated sympathetic blocks. Collier and his associates found that daily intravenous injections for up to three weeks gave considerable and sustained relief in a high proportion of patients with painful post-traumatic conditions in the extremities. Cooper and his co-workers<sup>5</sup> have reported that the drug sustains the circulation in the hind limbs of dogs after excision of the lower end of the aorta. In a control group nine out of ten animals died after one to seven days with cold, cyanosed, and paralysed hind limbs, while 16 out of 20 which received injections of tetraethylammonium chloride for three days survived with excellent function.

It seems likely, therefore, that the drug will be useful in the immediate treatment of sudden arterial occlusions especially since its administration is a simple matter compared with the manoeuvre of paravertebral sympathetic block. The latter is, however, probably more reliable and effective in practised hands. The tetraethylammonium compounds appear to have little beneficial effect in cases of Raynaud's disease and chronic obliterative arterial disease, mainly because their action is so transient.

## THE STRUCTURE OF MEDICINE

## HARVEIAN ORATION BY DR F M R WALSHÉ

The Harveian Oration was delivered before the Royal College of Physicians of London on Oct 18 by Dr F M R Walshe, FRS, physician in charge of the neurological department, University College Hospital, and physician to the National Hospital, Queen Square

In a discourse on "The Structure of Medicine and its Place among the Sciences" Dr Walshe began by quoting Harvey's famous injunction to the Fellows of the College, "To search and study out the secrets of nature by way of experiment," and he drew attention to a further passage in *De Motu Cordis*,

It has been shown by reason and experiment that the blood "—noting the sequence of the operations 'reason and 'experiment'" Harvey seemed to differ from John Hunter (Why think? Why not try the experiment?), but of course both were saying that reason and experiment could not be disjoined. In discussions on the intellectual structure of medicine there was too great a tendency to expound the theme in terms of hard antitheses—observation and experiment art and science—as though there was here a necessary dualism

Some physiologists showed a tendency to deny medicine its place among the sciences, they spoke of it as nothing more than applied physiology. Historically that was easily disposed of for the hospital was the cultural ancestor of the laboratory, and experimental physiology was born of therapy. But the physiologists' argument implicitly was that medicine did not carry its analysis of phenomena back to fundamental notions: it stopped at a half-way house, where it might borrow from other sciences. Even so, among the biological sciences medicine was not peculiar in this respect, and physiology itself had been eagerly borrowing from other sciences for the past hundred years. The truth surely was that every successive layer of thought in the annals of nature, living and dead from biology to physics, stopped at a half-way house when tracing its ideas back to their basic elements, yet each remained a field of discourse in its own right: one of the layers in the palimpsest of natural knowledge each with its own distinguishable intellectual content

## The Philosophical Approach

Dr Walshe proceeded to examine some fundamental notions underlying thought and activity in medicine. Such a philosophical approach was a means of escape from their own specialisms. Some generality of understanding was a craving need in medicine to be sought earnestly if they were not to decline to the level of craftsmen and technicians. In the many proposals for the reform of medical education offered within the past few years little more had been seen than superficial and uncoordinated attempts to grapple with the problem. None of these proposals had been informed by an adequate appreciation of those intellectual instruments and methods by which alone the confused data of physicians' experience could be transmuted into a more or less coherent body of ordered knowledge.

At the Renaissance when authority gave place to observation the study of those liberal arts by which alone the fruits of observation were expressed in a grammar of science, rhetorically expanded and logically interpreted was unhappily abandoned. He was referring here to the arts of grammar, rhetoric, and logic the *trivium* of the mediaeval undergraduate's curriculum. Some working knowledge of these liberal arts was an indispensable condition of the maintenance of medicine on the level of a true branch of learning.

A. N. Whitehead to whom the orator expressed indebtedness for the ideas put forward in his oration had said that "observation is selection." Observation was indeed a process of selection or discrimination—a process of selecting and discarding from the sum total of presenting objects. What was retained was retained in a subjective order of importance, and this observation involved some distortion of the impartial facts. Further all observation was subject to interpretation in terms of concepts. It was the product of many elements, and pure reason if indeed it existed as a mental operation had probably no scope outside the reading of instruments of precision and the casting of accounts. There was a continuous interplay between the conceptual and the observational orders of experience.

New observations modified the concepts, but, not less, new concepts led to fresh possibilities of observation

## Scientific Observation in Clinical Medicine

In no field of scientific observation was the presence of this complex of thought and feeling more obvious than in clinical medicine. The experiences there encountered were essentially random and not predetermined, and they had the incomplete and ambiguous character such experience of necessity possessed, and a particular urgency often attended their investigation. The trained observer constantly scanned the flux of presenting phenomena in search of those he had come to regard as pathognomonic, and when the facts he set down did not lie open to the observing eye, ear, or hand he used some formal test procedure to reveal them. In so doing he passed the indeterminate frontier which separated observation from experiment.

The very expression "clinical examination" seemed to suggest the formal grammatical significance which the term "observation" had come to possess. It indicated a picking and choosing according to ideas already entertained. Only the exceptional mind passed beyond the first exercise of this discriminating tendency, to take up a hitherto unobserved or unrecorded phenomenon and grasp its significance. "Indeed many a competent clinician may live out his professional existence never having made a truly original observation."

Simple observation, then, was not the purely rational activity some might have thought it. What was experiment? In part the answer was that the mind that observed was also the mind that devised, performed, and interpreted experimental observations. Experiment was but a method of providing observable data. The distinction between observation and experiment might be described as the distinction between the processes in law known as examination and cross-examination. Observation was the examination of nature, noting the data which lay open to inspection; experiment was cross-examination, forcing from nature by appropriate devices the answers it did not spontaneously yield.

In medicine, more perhaps than in any other scientific discipline, the data had to be taken in all stages of refinement and often in a high degree of incompleteness. When first encountered they were confused and ambiguous. They had to be sorted out, translated into the language and grammar of medicine, expounded by analogy, logically interpreted, and finally made to merge as clearly formulated propositions and as exemplifying the laws of nature. It was owing to the frequency with which important data were lacking that recourse had to be made to some other method than observation—namely, the method of experiment.

## The Experimental Method

The ultimate aim of the scientific observer was to grasp the principles inherent in the stream of evanescent phenomena, the role of experiment was to force this sublimation when it did not yield to simple observation. In an experimental observation the observer, guided by abstract ideas already formulated, standardized the conditions or set up an apparatus to make precise and relevant observation possible. He sought to isolate his material free from complicating factors so as to make it reveal its principles. To quote Whitehead again: "Experiment is a way of cooking the facts for the sake of exemplifying the law."

The method clearly involved an even higher degree of abstraction than simple observation, for many facts out of the presenting total were put in the discard. Perhaps that was why the experimental method, exclusively pursued, might prove somewhat narrowing to the mind, adversely affecting the philosophic generality of outlook and free play of ideas ranging over the sum of phenomena. But in both observation and experiment there was concentration of attention upon specific phenomena and some control of events.

The aphorism that "the only safe way to meet facts is to be well provided with ideas in good order" was brilliantly exemplified in Harvey himself. In his revision of the current theory of the circulation he was not merely employing experiment; he was speculating. It was to Harvey that medicine owed the example that both simple and experimental observation

were inseparable from the active entertainment of ideas and the courage to speculate logically. As Thomas Lewis said of Harvey in his memorable Harveian Oration of 1933, "It was because he possessed breadth of vision that he brought his studies to a conclusion that has proved fundamental to all medical science."

Too often people were inclined to equate the notion of "experiment" with that of animal experiment and to think of experiment as something divorced from the bedside and belonging to the laboratory, but in medicine the use of the lower animals was only a matter of expediency, owing to the severe limitation on the use of the human subject. The use of animals in experiment merely changed the matter but not the form of the experimental method. The routine clinical examination of a patient was a close-knit pattern of observation and experiment, especially perhaps in a neurological examination, though there did remain between this order of experiment and animal experiment the distinction that the former arose out of the investigation of the random material provided by disease, while the latter deliberately created a desired situation in a chosen material so as to compel the revelation of principles common to both the experimental and the human subject. In the one procedure, as in the other, abstract ideas acted as guiding principles. The intention in both was to provide data for observation and interpretation.

The increasing use and value of animal experiment were demonstrated in the contemporary history of medicine. It was playing an ever more essential part in the advance of medical knowledge. But the first and simple order of experiment—clinical experiment—should still be emphasized.

Every time we evoke an extensor plantar response by stroking the sole of the foot, every time we elicit a knee jerk, we are forcing certain spinal mechanisms by their mode of reaction to reveal internal conditions in the central nervous system that unaided observations by the five senses cannot tell us of. We are controlling conditions and isolating our material by a method that has all the essential form of the experimental method. Innumerable examples of a like order could be cited.

Again, the establishment of constant conditions of rest and activity, of nutrition, or of fluid intake—in fact, most of the procedures to which the patient under observation was subjected—were in their nature experimental. "The hospital ward is a laboratory in the fullest sense, is, indeed, the parent of all biological laboratories."

### Art and Science in Medicine

Dr Walshe next turned to a discussion of the respective roles of art and science in medicine. Here again, he thought, there was a tendency to lean too readily towards a hard antithesis, especially as the practical arts were continually being converted into the applied sciences. Such conversion was only to be expected, for the practical arts were operations according to rule, and rules upon examination were seen to be general propositions referring to particular cases and directed to future situations. Equally germane to the theme were the intellectual arts, and here the problem became not that of art and science but that of art in science.

The way in which the confused data of direct experience were transformed into the clearly formulated propositions of a rational science was by the use of those liberal arts he had already mentioned. For the trained mind every complex of presenting phenomena was a text to be read, translated into the grammar of science, rhetorically expanded, and logically interpreted. Thus in diagnosis the signs and symptoms were noted and translated into a technical language—that is, into an artificial linguistic construction which came to stand for phenomena. A complex process of classification in this language then ensued, signs and symptoms were grouped into patterns and sequences. From these patterns and sequences what might be called their space-time relationships were clarified and the future course of events predicted—the process known as prognosis.

There were further terms in the light of which the original data must be considered. The total complex must be considered in terms of a departure from normal function, of a reaction to endogenous or exogenous nova, and of the Aristotelian modes of causation—in other words, a physiological, a pathological and an aetiological analysis. Finally there came the

logical interpretation and synthesis of the data thus derived from which emerged natural laws and general principles. This was the method of science, but who could deny that the gift of insight, the ability to discern and develop analogies, to detect patterns and sequences, and to interpret logically were intellectual arts, varying from individual to individual, but constituting an integral element in scientific thought and activity in its best?

He touched briefly on the correlation of the ancient arts of grammar, rhetoric, and logic with diagnosis, prognosis, and therapy in medicine, and with observation, prediction, and experiment in laboratory science.

### Academic Medicine in Peril

In his concluding passages Dr Walshe appealed especially to professors of medicine for the highest degree of understanding of the foundations of thought and action in medicine so that future practitioners might be prevented from declining to the level of craftsmen and technicians and the profession from becoming a chaotic muddle of technologists. How could medicine be worthily taught on its academic side unless by minds well versed in the liberal arts, understanding the principles on which knowledge was ordered, and capable of expounding and showing in action the reasoning methods involved?

"The need for rebuilding the foundations of medicine was never greater than to day, when we are being swept along on a spate of new knowledge and new techniques, and have so little time for their due contemplation and integration. If some philosophy of medicine does not find a home among us [in this College] where shall this be found? Not, it is increasingly apparent, in the modern university, nor in a Ministry of Health, and, if we do not show ourselves eager to promote such a philosophy, then the sum of our corporate activities as a College, whatever their immediate importance, becomes trivialized. History does not record what book it was that William Harvey was reading as he sat under a tree with the two younger sons of Charles I at the battle of Edgehill, but we may be sure it did not deal with consultant services nor with the pay and grading of specialists."

The Royal College of Physicians, if it was to survive as something significant in the intellectual life of medicine, must remain a fountainhead of academic medicine, of true learning, the home wherein a philosophy of medicine found a permanent abiding place and disciples eager to learn and teach, and where the liberal traditions of medicine could look confidently for their defence against the constant threat of debasement by the technical arts and by the spiritually and intellectually oppressive materialist dogmas of the present day.

## ASPECTS OF RHEUMATIC DISORDER

### DR PHILIP HENCH'S LECTURES

On Oct 13 two lectures were given by Dr Philip S. Hench, Associate Professor at the Mayo Clinic, the first at the West London Hospital, where Dr Hench spoke on psychogenic rheumatism, and the other to the Section of Physical Medicine of the Royal Society of Medicine, where he made a critical evaluation of current remedies for rheumatoid arthritis.

### Psychogenic Rheumatism

In his first lecture Dr Hench said that there were about 200 conditions which the layman called rheumatism. About half of these were forms of arthritis, and the others were musculo-skeletal conditions. Some 85% of "rheumatic" patients had one or other of the following conditions: rheumatoid arthritis, osteoarthritis, rheumatic fever, fibrositis, psychogenic rheumatism, gout, or gonorrhoeal arthritis. Osteoarthritis was a composite of degenerative chondritis, osteitis, and fibrositis, with no significant synovitis or systemic disease. Rheumatoid arthritis was a composite of proliferating synovitis, osteomyelitis, destructive chondritis, and secondary fibrositis, with systemic disease. In America and probably in this country the diagnosis of arthritis was made too indiscriminately. The criteria for diagnosis should be as definite as for pulmonary tuberculosis.

Of the many terms used to describe psychoneurosis manifested by musculo-skeletal symptoms he preferred "psychogenic rheumatism." It connoted no rheumatic disease. Psychogenic rheumatism was one of the commonest of disorders. It was manifested by pains in the muscles or joints or in both. It might

exist alone or as the functional overlap of some traumatic disorder. In its primary form it was not related to organic disease, in its secondary form it was so related. It might be a functional prolongation of a recently healed condition or a superimposition of functional symptoms on a relatively minor condition such as traumatized joint or mild fibrositis.

Fibrositis was the chief rheumatic disease from which psychogenic rheumatism must be differentiated. In general, fibrositis placed its victim at the mercy of change in external environments (such as heat or cold), while psychogenic rheumatism intensified or receded with change in internal environment (mood, excitement, worry, fatigue). The patient with psychogenic rheumatism was tense, anxious, defensive, antagonistic—I cannot describe it, doctor, it is like . . . The chief symptoms were tension, weakness, numbness, tingling, queer or tired sensations—hurting all over, as the patients expressed it—and continuing day and night. Mental preoccupation gave marked relief, but he paid for it afterwards. The pains followed no anatomical pattern. Stiffness was minimal or absent. In the psychogenic patient fatigue caused disability, whereas in the fibrositic patient disability caused fatigue. The psychogenic patient often showed aversion to remedies—“Nothing will help me, doctor.” Physiotherapy had variable results, sometimes making the patient worse. There was resistance to examination—the “touch me not” reaction—whereas in fibrositis the examination found a co-operative patient.

Dr Hench mentioned, in recent cases of his own, the factors which had brought about psychogenic rheumatism—stern parents interfering with the child's social development, unattractive girl dominated by mother, “imprisoning” by parents, one vacation in ten years, sexual impotence, June and December marriage, sacrifice of marriage for dependent parent, unfaithful, indifferent, or drunken spouse, father imprisoned for embezzlement—and so through many other fears and frustrations.

Dr Spencer Paterson, psychiatrist to the West London Hospital, who followed Dr Hench, said that it still remained difficult to assess the significance of the accompanying neurosis. He could not help wondering whether in Service cases the fundamental difficulty was not the inadequacy of the patient for the life he was called upon to live, and the development of the neurosis represented failure to meet the stresses of military service. It was quite possible for a patient to translate his emotional conflict into pain.

Dr Hench replied that in the US Army during the war psychogenic rheumatism was far down in the list of neuroses. He added that the pun that these patients endured was real, and he always impressed upon them the following, “Now, I have not said that your pain is imaginary, it is real, and it is just as severe as you say it is. Don't go home and say I said it was ‘all in your head.’ And don't go home and say that nothing can be done for it, many things can be done for it.”

#### Current Remedies for Rheumatoid Arthritis

In his second address, which was the Samuel Hyde Lecture of the Section of Physical Medicine, Dr Hench, saying that he had nothing striking or wonderful to bring before his audience, discussed critically the current remedies for rheumatoid arthritis.

He put forward a basic programme of general measures for supportive treatment: (1) Increased rest for affected joints. (2) Physical therapy daily. (3) Simple analgesics. He thought they were remiss as therapists in failing to give the patient the relief which these afforded. (4) Nutritious diet (high calorie intake and vitamin supplements). (5) Removal of definitely infective foci as a non-specific measure. (6) Prevention of deformity by simple non-surgical or protective measures. He analysed the reports of a number of observers showing that these simple medical and orthopaedic procedures used alone brought about the inactivation of the disease in 15% of cases and improvement in varying degrees in 38%, a total of significant results in 53%. When however this basic programme was combined with special measures such as gold therapy, a similar analysis showed a quite satisfactory permanent result in 25% and improvement in 50%. The significant results thus making 78% as compared with 53%.

The remedial nature of rheumatoid arthritis was sufficiently obvious that the number of remedies put forward for it

Dr Hench showed a slide in which a remedy was listed for every letter of the alphabet, even including Z—“zero therapy” (do nothing). The most promising field appeared to be chrysotherapy, with new “safe” preparations, new methods of administration, and the use of BAL for controlling toxic reactions. Much was claimed for certain new gold preparations—calcium aurothiomalate and gold thioglycolanilide—which were said to be far less toxic than other forms, but with the former of these compounds certain reactions, sometimes severe, in the skin and mucosa had been noted. Colloidal gold was ineffective therapeutically, the colloidal particles were phagocytized by the reticulo endothelium and little or no gold appeared in the plasma. With insoluble gold compounds the absorption and elimination varied and toxic reactions were prolonged.

The old method of administering gold salts involved weekly 100-mg injections until 1–1.5 g was given. This had disadvantages in increasing the number of relapses and the toxicity. The new method consisted of weekly doses of 50 mg until 1–1.5 g had been given, followed by small maintenance doses of 25 or 50 mg bi-weekly for several months. With this method it was claimed that 80% of the gold was retained, the plasma content was constant at 0.4–0.8 mg per 100 ml, and excretion in the urine was constant also—about 1 mg daily.

Dr Hench also analysed the reported results of various workers on the use of BAL for severe gold toxicity. In 17 out of 18 cases of gold dermatitis there had been prompt cure. Altogether the balance sheet for chrysotherapy on the basis of recent reports was, on the credit side, complete remission in 10–15% of cases and definite improvement in 50%, and there were no reactions in 50% and mild or moderate reactions in 45%. On the debit side, little or no relief was afforded in 35% of cases, and severe though non-fatal reactions were experienced in 3–5% and (prior to BAL) fatal reactions in 0.4%. Controlled studies indicated that chrysotherapy was of definite value. It was the only treatment which would change fairly promptly the course of the disease in a significant percentage of cases. It might accomplish in six months or less what nature or general measures might take six years or more to achieve.

Copper salts had been recommended for chronic polyarthritis by some workers, and Forestier and others claimed improvements with an intramuscular preparation, cupro-oxyquinoline sulphionate, but in America they had found the results disappointing.

#### Miscellaneous Remedies

Among many miscellaneous remedies for rheumatoid arthritis streptomycin had not come up to expectations. Penicillin had no significant action on the course of the disease. Another preparation for which something was claimed—antirheumatic cytotoxic serum (ACS)—had given mostly negative or inconclusive results. There was no direct indication of any antirheumatic action of vitamins. In fact, the crowd of remedies reminded him of a cartoon in an American paper in which a hostess was shown introducing a distinguished doctor to her guests—“This is my friend Dr—, who has invented a cure for which there is no known disease.”

He passed in rapid review some of the remedies offered—for example, sodium gluconate, intravenous infusions of procaine, intragluteal injections of tubocurarine for relief of muscle spasm, this last a rather cumbersome and unsatisfactory way of handling a static situation, though it might be used in emergency. The results of radiotherapy were unpredictable. Venom (bee or cobra) had been advocated, and even extract of red ants. Transfusions of blood from pregnant women had been used, and he analysed the reports of seven workers from 1943 to 1948 comprising 113 cases, 5% of which were said to be “cured” and about 50% improved, but he said he was not impressed by these figures. The use of blood transfusions in rheumatoid arthritis gave very variable results. He also analysed 18 reported cases in which splenectomy had been performed in chronic polyarthritis, with marked improvement in 1, mild improvement in 7, and temporary improvement in 2, but if there was an abnormal blood picture it might be restored to normal. It must be supposed that radiotherapy had some use in rheumatoid spondylitis.

Finally, he mentioned the remissions induced by spontaneous jaundice, ranging from 64 to 96% in reported cases and the remissions induced by pregnancy, ranging from 70 to 93%. These figures indicated that there was an unrealized potential

in these conditions which they did not know how to reproduce in treatment. The conclusion might be drawn that rheumatoid arthritis was potentially reversible and eventually would become therapeutically controllable. To the task of making it so they must bring new enthusiasm, new ideas, and new courage.

Dr C W Buckley said that the lecturer had not mentioned the use of sulphonamides in rheumatoid arthritis, as to which there had been two publications, one from America, putting forward opposite opinions. Dr Hench replied that in America they were not enthusiastic about the use of the sulphonamides in this condition. A good many of his friends used them, but they never published their results because the improvement was so transient.

## CONFERENCE ON STREPTOMYCIN MEMORANDUM FOR WHO

At the third session of the Interim Commission of WHO held at Geneva in April, 1947, it was resolved to set up an expert committee on tuberculosis. In the first report<sup>1</sup> of this committee the various field activities and techniques for tuberculosis control were set out, and it was stated that the best contribution which WHO could make to tuberculosis research would appear to be in developing and recommending uniform procedures. Special problems would require the services of subcommittees expert in highly specialized fields. Among the most urgent of these problems was the evaluation of new chemotherapeutic agents such as streptomycin, and a conference on streptomycin therapy in tuberculosis was convened in New York on July 30 and 31. The following experts attended: Professor K. Choremis (Greece), Professor C. Cocchi (Italy), Dr Robert Cruickshank and Dr M. Daniels (United Kingdom), Professor R. Debré (France), Professor R. Dubois (Belgium), Dr H. Corwin Hinshaw and Dr H. McLeod Riggins (USA), with Dr H. E. Hilleboe (USA), a member of the parent committee, as chairman. In addition, Americans expert in different fields of streptomycin therapy and in the pathology and bacteriology of tuberculosis were invited to attend the meetings.

### American Trends

In the first three sessions the discussions covered the general principles of chemotherapy in tuberculosis, the results obtained with streptomycin in different forms of tuberculous infection, studies in combined chemotherapy, and laboratory methods for the diagnosis of tuberculosis and for the control of streptomycin therapy. The reports of members from some European countries gave a strong impression that acute tuberculosis in childhood (tuberculous meningitis and miliary tuberculosis) was much more common there than in the USA, and that the results with streptomycin in these acute infections of childhood were more encouraging than earlier reports had suggested. The present position in America was reviewed by Dr J. Barnwell of the Veterans Association, who analysed over 3 000 treated cases, by Dr Hinshaw, representing the Trudeau Society, and by Dr Riggins of the American Tuberculosis Society, while Dr Floyd Feldman outlined the trials now being sponsored by the US Public Health Service. The tendency in American centres is to reduce dosage to 1 g per day or 20 mg per kg body weight, with a resultant reduction in toxic reactions but with little obvious change in therapeutic effect, and to shorten the duration of treatment to 60, 42, or even 28 days in cases of pulmonary tuberculosis in the hope of preventing or minimizing the development of streptomycin-resistant strains of the tubercle bacillus. Remarkable results were reported by Dr Edith Lincoln in the treatment of small groups of cases of tuberculous meningitis and miliary tuberculosis with streptomycin and promizole (a sulphone compound) the latter drug being continued for many months after streptomycin therapy was stopped. Dr Daniels described the organization by the Medical Research Council of streptomycin trials in tuberculous meningitis, miliary tuberculosis and progressive bilateral pulmonary tuberculosis. Laboratory methods were discussed by Dr Cruickshank and Mr W. Steenken while Dr Rene Dubois made a strong plea for discarding 'egg-concoctions' in favour of the oleic acid-bovine albumin diagnostic medium for the isolation of the tubercle bacillus.<sup>2</sup>

At the final session, attended only by members of the WHO subcommittee, recommendations were drafted concerning the use and value of streptomycin in tuberculosis. The following points were stressed:

In most forms of tuberculosis streptomycin is at best an adjunct to other recognized therapies: its use is not devoid of risk in the development of toxic reactions, and, more serious, of streptomycin-resistant tubercle bacilli which may be transmitted to exposed contacts. The drug should at present be distributed through Government or other responsible health agencies to hospitals and institutions where it can be used under expert supervision. Patients with tuberculous meningitis and miliary tuberculosis, in whom the use of the drug can be a life-saving procedure, should have priority. In certain other forms of tuberculosis—e.g., acute pulmonary, tracheo-bronchial sinuses, and fistulae—streptomycin, judiciously used, could be a useful adjunct form of therapy. Size and duration of dosage could not yet be defined within narrow limits. The wide variations in methods of reporting the results of streptomycin treatment from different centres made comparison of the efficacy of different therapies impossible, and the committee urged the adoption of certain minimum standards of reporting which will render such comparisons possible and valid. WHO should continue to encourage and facilitate international study and co-operation in researches on the chemotherapy of tuberculosis.

The memorandum embodying these recommendations has now been accepted by the Tuberculosis Expert Committee and forwarded for approval to the Executive Board of WHO. After the conference the delegates had a most enjoyable week-end outing to the Homer Folks Sanatorium, Oneonta, belonging to the New York State Department of Health, where many clinical and laboratory problems in the streptomycin therapy of tuberculosis were discussed in detail.

## Reports of Societies

### POLIOMYELITIS IN ENGLAND AND WALES

The meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine, held on Oct 4, with Sir Allen Daley in the chair, was devoted to the recent history of poliomyelitis in England and Wales.

Dr A. H. GALE said that the statistical raw material for a study of poliomyelitis was even more unsatisfactory than for most of the other communicable diseases. Its defects were due to a large extent to the nature of the disease. The returns from the hospital survey which W. H. Bradley and he carried out during the epidemic of 1947 showed that among 6 762 patients admitted to hospital with a diagnosis of poliomyelitis or polioencephalitis the diagnosis was subsequently confirmed in about 70%. If they desired to have patients admitted early they must resign themselves to that order of error in the original diagnosis. In comparison with previous outbreaks the epidemic of 1947 was remarkable rather for its wide distribution than for any very high incidence in particular localities.

Where special inquiries were made the number of deaths was found to be rather smaller than was to be expected from the Registrar General's figures. The possible explanation was that an appreciable number of deaths occurred every year from obscure nervous diseases, and often these were recorded in the certificates to poliomyelitis and polioencephalitis, though whether they were really due to these causes was doubtful. The age incidence was generally considered to have risen during the last thirty years, though it had been suggested that this was apparent only and was due to the ageing of the population. This latter suggestion, however, was not borne out by a study of the figures. In the 1912-13 experience the incidence in the age group 5-10 was only 27% of that in the age group 0-5 and in the age group 10-15 only 8%, whereas in 1947 the incidence in the age group 5-10 was 84% of that in the age group 0-5 and in the age group 10-15 it was 62%. The change in age of the population, therefore, would not explain what had happened. In 1947 the rate for the age group 15-25 was 36% of that for the age group 0-5. The distribution of notification in the early stages did rather suggest that they had in poliomyelitis an endemic disease which became epidemic rather than an importation from some outside source.

### Field Investigations

Dr ALLAN MCFARLAN referred to the Malta epidemic of 1942-3 and to the epidemics in Singapore and in Mauritius, in all of which there was a very sharp incidence lasting only for a few weeks, with a sudden rise and an equally sudden fall. Last year, when a widely diffused epidemic occurred in England and Wales, he set out to discover whether it showed the same characteristic. In Essex he found the same kind of geographical spread along the main lines of communication as he had seen in Mauritius. In Eccles, Lancashire, again, there was an early geographical localization, and here also there was a high peak incidence. From various parts of the country he collected material relating to more than 900 cases. Among these were only 23 instances of two cases in the same family, and one instance of three cases in the majority of these cases the second had occurred within ten days of the first. The age distribution of the cases of which he had particulars was very much the same as in the cases of Bradley and Gale. Among 24 cases from rural districts in Essex there were three in which direct contact was shown, six of the other patients had been in London from seven to fourteen days before their illness began, and in three other cases a visitor from London had come to the house or another member of the family had been to London in the same period. Of the cases gathered from the whole country 42% had not been away from home during the three weeks before onset. It might be that the shift in age incidence could be elucidated a little further from the figures obtained by field investigation. Instead of the former 60 or 80% of the patients being under 5, those under that age in these cases in 1947 represented only one-third of the total. At the same time there were slight differences in incidence between occupational groups and between families who had baths in their houses and others who had not, and so forth.

Dr A R WILLIAMSON mentioned the epidemic as it affected Nettlebed, a village on the main London-Oxford road, situated on the lower Chilterns. From July 23 to Sept 12, 1947, there occurred 20 cases of an obscure illness, six of which he notified as poliomyelitis, he thought that perhaps he should have notified all 20. It was an explosive outbreak, and the cases followed a remarkable periodicity, with one week intervals between fresh infections.

Mr BENJAMIN, of the Statistical Department of the London County Council, gave some account of the 1947 outbreak in London. No special interest attached to the London map showing the distribution of cases geographically. Certain different levels of attack were found in the different administrative areas, but no association was discovered between attack rate and social condition. The problem was viewed from the immunity angle, the attack rate being compared with the record of the previous ten years in the particular borough, but again there was no significant association. Nor did a study of the question in relation to returned evacuees appear to discover any significance. The epidemic curve in London was relatively smooth, without the sharp peak encountered in some other parts of the country.

Dr W P SWEETNAM gave an account of the epidemic in the Lancashire borough of Eccles (*British Medical Journal* 1948, 1, 1172), and Dr C O STALLYBRASS commented on the absence from the discussion of any reference to milk transmission—first referred to, he thought, in the outbreak in Liverpool in 1898—or of school infection.

### DIET IN HOSPITALS

A meeting of the London County Medical Society (the new name for what was the LCC Medical Society) was held at Friends House on Oct 7, under the chairmanship of Dr R C HARKNESS, when the subject of 'Nutrition in Hospitals' was discussed.

Dr MAGNUS PYKE said that no stockbreeder would accept the principle that he should give his stock a diet only sufficient to prevent deficiency disease. The minimum cost diets for human consumption which were produced by economists were open to criticism on that score. Even the low-cost diet given in the B M A Nutrition Committee's report of 1933 was capable of improvement. The rational approach to a satisfactory diet had been suggested by Sir John Boyd Orr when he said that the proper consideration should be whether the diet contained

optimal amounts of all nutrients. Of calories it might be thought that at this time of day it was unnecessary to say anything, yet some recognized diets were inadequate in this respect. On the question of protein there was a signal lack of agreement among investigators with different outlooks. Experimental physiologists gave one figure, and observers less restricted in their interests a very different figure. Statistically it had been shown that there was a high correlation between efficiency in its widest sense and a rich protein intake. In recent years it had been customary to pay comparatively little attention to the protein component in normal diet—'Look after the calories and the proteins will take care of themselves'. The estimate of 1 g protein per 1 kg body weight had been made. But there was an additional factor arising during illness to which the hospital dietitian must pay special attention. During many illnesses there was a disturbance of protein metabolism and numerous workers had recommended high protein diets in a wide variety of diseases. There were three good reasons why those responsible for hospital diets should pay attention to supplies of protein: (1) because the caloric requirement for patients in bed was reduced it was not safe to assume that the protein intake might be reduced *pari passu* without disadvantage, (2) a special need for protein might arise as a result of the condition for which the patient had been brought to hospital, (3) hospital diets should be a model for and a guide towards the perfect diet. A rich protein diet would be one containing milk, and the milk would contain calcium. An improvement in the usual and often inadequate level of calcium in the British dietary might prove to have been one of the best methods of benefiting health. The national policy of fortifying flour with calcium appeared to be amply justified.

The vitamin-A problem, Dr Pyke continued, was complex, and its complexity had led unfortunately to a sceptical attitude about the value of vitamin A in the diet. Disturbances of vitamin-A absorption had been shown in a number of pathological conditions, including diabetes and certain fevers. One more nutrient to be mentioned was vitamin C which was easily lost in cooking. An adequate supply of vitamin C was a constant preoccupation of those responsible for hospital diets. Here again it was not possible to be satisfied only with a minimum. The U.S. National Research Council gave an intake of 75 mg of vitamin C daily for the normal man and 70 for the normal woman. Vitamin C was important in the treatment of injuries and following operation again many of the common drugs affected the excretion of vitamin C. Ammonium chloride, for example, caused a substantial increase in excretion and the same was true of aspirin, the sulphonamides, chloroform and other anaesthetics, and of many other substances. In 1943 the King Edward's Hospital Fund survey revealed a deplorable state of affairs in some hospital dietaries. Since then efforts had been made to improve the diet. But material progress could not be achieved without other measures in addition to ensuring the adequacy of nutrients. One necessity was a better handling of the food, and another was attention to the aesthetics of meals. A large part of the attraction and appetizing value of a restaurant meal was in the manner of its service, and the same was true for patients in hospitals.

Miss SIMMONS, dietitian of Hammersmith Hospital, asked why hospitals should tolerate a second-rate dietetic service. It was to be hoped, she said, that hospital kitchens would be brought up to date by necessary structural alteration and by the appointment of qualified cooks, who should have a higher status and an adequate salary. Many special diets in hospitals were necessary only because their nutritional values were higher than the ordinary diet, and if more attention were paid to the latter the need for some special diets would disappear. One dried milk per day was allowed for every hospital patient and enabled a store to be accumulated for emergencies. She favoured a system whereby food, kept hot on trolleys, was served in the wards in such a way as to permit patients a certain choice. It had been suggested that it was waste of time for nurses to serve food to patients, but surely feeding the patient was a form of nursing and gave opportunities for observation of the patients. The preparation of the food, however, should not be part of the nurses' work. Miss Simmons concluded by saying that there was no reason why the same general high

standard of efficiency that was maintained in the best hotels should not also be maintained in hospitals

In some general discussion it was suggested that the fact that patients obtained perhaps 30% of their calories from food sent to them from outside the hospital did not necessarily prove that hospital diet was inadequate, and in fact one constantly saw food returned after ward meals. The superintendent of a tuberculosis hospital said that 4,000 calories was the standard in his institution in pre-war days, but since the rationing system came in it had dropped to 3,500 calories or less. This speaker also expressed the view that food waste in hospitals, which could not be measured without great difficulty, was higher where the diet was richer. Another speaker urged the desirability of changing the routine whereby the same dishes were served on the same days of the week.

## DEVELOPING NEW DRUGS

### FINE CHEMICALS GROUP

The Fine Chemicals Group of the Society of Chemical Industry held its inaugural meeting at the Royal Institution on Oct 5. Sir JACK DRUMMOND FRS, chairman of the Group, presided, and the inaugural address was delivered by Professor J H BURN.

Professor Burn said that the work of pharmacologists obliged them to watch the development of new medicaments in industrial laboratories, and he had always believed that the university worker should be willing to assist industrial laboratories if he could, as a matter of public service. After recalling the early history of the production of fine chemicals for medicinal use and discussing the development of the manufacture in particular of the arsphenamines, Professor Burn suggested that, but for the discovery of the value of sulphonamides and the consequent revindication of chemotherapy, it was possible that the use of penicillin might still be unknown. One reason for the long interval elapsing between Fleming's discovery of penicillin in 1929 and the demonstration of its curative value in 1941 was that in the early thirties there prevailed a widespread belief that 'an antibacterial agent for use in man was an impossibility'. Professor Burn referred briefly to the work of Fourneau which led to 'stovaine' and 'stovarsol', and to the introduction of the first antihistamine substance, neoantergan (anthisan), by Bovet in 1944, a year before 'benadryl' was discovered by Loew, Kaiser and Moore.

As examples of important work on fine chemicals in this country Professor Burn instanced in the academic field the synthesis of thyroxine by Harington, the isolation of muscarine and *d* tubocurarine by King, the preparation of stilboestrol by Dodds and Robinson, the preparation of penicillin by Chain and Florey, and the discovery of BAL (dimercaptopropanol) and its properties by Peters, Stocken and Thompson. In the industrial field he mentioned the work of Glenny on diphtheria prophylactic and antitoxin, the introduction of large-scale manufacture of insulin in this country by Carr in conjunction with Dudley, the work of Sydney Smith on 'digoxin', of Ewins on stilbamidine and on sulphapyridine, and "the admirable work of Curd, Davey, and Rose on paludrine". After quoting from Sir Henry Tizard's presidential address to the British Association in September, Professor Burn said that it was not merely more research that industry needed to day so much as increased application of what was already known. There must be many more men in executive positions in industry whose practical experience had been preceded by a scientific education. Directors must not merely be good business men who sought advice from scientific subordinates, the scientists must actually take a part in direction. Further, the value of industrial scientific workers could be increased by allowing them to spend a few months in academic laboratories where new technical methods could be learnt and also by submitting them to a minimum of rules and allowing a maximum of freedom. "If the clock is forgotten and provided the head of the department sets an example many scientific workers will voluntarily work ten or twelve hours daily."

### Immediate Objectives

Professor Burn referred to work on tuberculosis, in which, notwithstanding streptomycin the diphenylsulphones and *p* amino-salicylic acid, he considered the great discovery had yet

to be made, virus infections, in which chloromycetin and a nitroacridine made in the Höchst laboratories might become important, and cancer which still remained for the most part an unsolved problem. It was one thing to deal with bacteria in the blood and extra-cellular fluids, and quite another to destroy agents which lived inside the cell or even in the nucleus. More rapid progress might be expected in veterinary medicine because the application to animal and bird diseases of the advances made since the introduction of the sulphonamides had not yet been fully worked out. Many new problems of drug administration had arisen and offered scope for profitable investigation. Turning to the work of university pharmacological laboratories, Professor Burn said that despite the criticism that too much time was spent investigating problems of academic interest which, because of the very methods used, could not be expected to lead to a fundamental discovery, the importance of elaborating quantitative methods for the estimation of biological properties was indisputable. Since 1926 chemical work had been greatly facilitated by the introduction of methods of biological standardization, the principles of which were now universally accepted. Tribute was due to Sir Henry Dale for gaining acceptance of the principle of comparative methods and of the necessity for international standards. He thought the decision of the Pharmaceutical Society to establish a laboratory for the study of biological standardization had had an important influence, for it compelled a concentration of attention on standardization which would not otherwise have been attained.

Another contribution of the academic pharmacologist stemmed from the classical work of Dale and Laidlaw and their colleagues Carr Barger, and Ewins on adrenaline and sympathetico-mimetic amines, and on histamine and acetylcholine. More and more did it appear from subsequent work that adrenaline, histamine, and acetylcholine were three substances which the body used for many different purposes. It now seemed that a large number of chemical substances acted in the body by modifying or interfering with the action of adrenaline or histamine or acetylcholine. It was possible that local anaesthetics and analgesics were substances which antagonized the action of acetylcholine at sensory nerve endings or in other parts of the central nervous system, and that the power of substances to lengthen the refractory period of heart muscle might be related to their antagonism to acetylcholine in the metabolism of cardiac tissue. The interrelation of properties of local anaesthetics, spasmolytics, and analgesics made it worth while to examine all compounds prepared to exert one of these properties for its possession of the others. A substance introduced as a local anaesthetic, for example, might be a still better spasmolytic. It was probably because antihistamine substances possessed the other properties that they produced side effects. The grouping together of many properties as fundamentally the same was useful in that it brought some order into the long list of apparently unrelated plant alkaloids. The similarity in many properties of atropine, papaverine, and quinine, and of conessine from *Kurchi* bark and quinine, suggested points of biochemical similarity which assisted towards an understanding of their relationships.

## Preparations and Appliances

### OPERATING SPECTACLES

A surgeon writes. Ultimately most surgeons wear glasses to operate. Ordinary spectacles steam up when one is masked for operation. By the application of a special preparation or of soap, and by polishing the lenses, this can be avoided.

This is satisfactory, but it is quite frequently overlooked. A further way to eliminate this blurring by condensation is by using glasses with small lenses which allow the free circulation of air around them. A pair of such spectacles which have proved satisfactory in practice have been made by Messrs Dixey who tried various shaped lenses until those illustrated were arrived at.

**A Delicious Concentrated  
VITAMIN FOOD**

VIMALTOL presents special advantages to the physician requiring a product which incorporates important vitamins in a form entirely pleasant and acceptable to every patient.

Vimaltol is made from specially prepared malt extract of high protein content yeast—one of the richest sources of vitamin B<sub>1</sub>—and Halibut Liver Oil, an important source of vitamins A and D. It is also fortified with additional vitamins and mineral salts and is deliciously flavoured with orange juice.

Vimaltol is standardized to contain in each fluid ounce 648 international units of vitamin A and 1390 of vitamin D, also 0.3 milligrammes of vitamin B<sub>1</sub>, 4 of Niacin (P.P. vitamin) and 4.8 of Iron in a readily assimilated form.

Vimaltol the many of one or everyday dietary      atment of deficiency in average

The routine use of Vimaltol helps normal development of the growing organism and the maintenance of correct metabolism while raising the general resistance against infection.

## Correspondence

### Globin Insulin

SIR,—Perhaps you will allow me to reply to the letters about my paper on globin insulin (July 24, p 191). Three main criticisms are made.

First, your leading article (p 209), Dr Ian Murray (Aug 7, p 313), and Professor D M Dunlop and Dr J B Donald (Aug 14, p 352) sound a warning against oversimplification with, it is implied, inadequate control. My experience shows that adequate control is attained in a large number of cases by one dose of globin insulin a day, and it is surely in the interest of the diabetic person that his regime should be simple and should interfere as little as possible with his working life. Those who have used globin insulin agree that it is useful in mild and moderate cases, and since 70–75% of ambulant patients need less than 40 units of insulin they come into this category. The question of stability is different, and I should have expressed my conclusion better if I had written 'stable and uncomplicated cases'. Many diabetics on large doses of insulin are stable and do well on globin insulin (I gave examples). The unstable are fortunately a small minority, their insulin needs may be large or small, and the instability is often due to a complication such as renal disease lowered renal threshold, or flightiness of life. As Dr Murray points out multiple doses of soluble insulin are the only means of attaining a reasonable balance.

The second point made in your leading article and by Dr R D Lawrence (Sept 18, p 572), is that globin insulin is too much like Hagedorn's delay insulin to be of any use in a single dose. This dictum does not correspond with experience. The duration of action of any insulin is due to the rate of absorption, which varies with factors other than its own properties—e.g., the magnitude of the dose, the condition of the skin and subcutaneous tissues at the site of injection, and the state of the circulation. Globin insulin resembles delay insulin in that the average duration of action is longer than that of soluble insulin and shorter than that of protamine zinc insulin. Experience has shown that it controls the blood sugar during the 24 hours in the majority of cases and that it is less prone than PZI to give reactions at night. The fact that reactions have occasionally occurred in the early hours of the morning is a further proof of the length of action. In only a minority of cases it fails to control the blood sugar in the evening and night.

The third question concerning diet is raised in your leading article and by Dr Murray. They stress the importance of constancy, I agree that constancy is a *sine qua non* in the success of all insulin therapy, and I indicated how the principle is carried out by my patients. Dr Murray takes exception to one of my examples who stated that he eats 'mountains of bread and potatoes'. Although this is an "uncertain quantity" as measured by scales (surely now passed into the limbo of the Allan era), it does not vary from day to day. The diet of an English farm worker who omits sugar and jam is regular, monotonous, and constant to a degree difficult to attain in towns even under rationing. The boy is subject to the temptations of a large family, school, ice creams, etc. His mother is intelligent and conscientious, and he is not allowed sugar or jam and in actual fact maintains a steady balance.

I hope that the experience with globin insulin which I have described will encourage its wider use. It has suffered from the argument, 'Globin insulin is identical with delay insulin'—a false premise—"delay insulin in a single dose was not successful"—was it extensively tried?—therefore globin insulin will not control the blood sugar during the twenty-four hours. My answer is that it does—I am etc.

### Post-gastrectomy Syndrome

SIR—On reading Dr W T Irvine's article (Sept 11, p 514) I felt that my own experiences as being slightly different from his findings, might be of interest. I underwent partial gastrectomy in August 1947 for duodenal ulcer of 10 years standing, and on leaving hospital was very soon eating con-

siderably larger meals of any and every food than I could before operation, without any untoward results except on one occasion when I was very sick after drinking a cup of cream in mistake for milk.

Soon after returning to work in December I began to experience severe nausea on getting up, 20 minutes or so after a good strong cup of tea with plenty of sugar. This generally put me off my breakfast bacon and eggs and persisted till about half-way through the morning surgery, but on several occasions was only relieved by vomiting. Most mornings at about 10.30 or 11 o'clock all the symptoms then described by Dr Irvine started—giddiness, dizziness, sweating, tremor, and feeling faint. These responded within a few minutes to large doses of carbohydrate, though on one occasion it needed two cups of hot milk with 2 oz (60 g) glucose, a bar of chocolate, two pieces of cake, and two bananas.

Later I began having nausea immediately after tea as well. Having by then lost over a stone in weight, I was advised that the nausea might be due to tea and coffee. I gave these up and took a few ¼-gr (16 mg) tablets of phenobarbitone, and the symptoms both of nausea and post-prandial dizziness etc., disappeared completely and have so far only recurred slightly during the early morning while cruising in a sailing yacht.

It would seem therefore that in my own case the symptoms could not have been due to the bulkiness of the meal, occurring as they did after a light breakfast of tea and cereal with plenty of glucose and sugar and after afternoon tea with again plenty of honey, treacle, and sugar in the tea. Incidentally my symptoms were exactly the same prior to operation and responded to exactly the same treatment.

Blood sugar tests revealed a considerable hypoglycaemia the curve being at its lowest at about the time of onset of symptoms. Dr Irvine's suggestion that these might be caused by stimulation of the sympathetic system is interesting. Might worry be one of the precipitating factors? I gave up worrying after July 5—I am, etc.

Shanklin I O W

F LINDSAY DICKSON

### Carcinoma of the Breast

SIR,—The article by Sir Cecil Wakeley (Oct 2 p 631) on carcinoma of the breast is of great interest as it reviews his conclusions from a wide experience of the subject. The technique of radical excision which he describes starting with the clearing of the axilla and continuing down the lateral chest wall and leaving the reflection of the medial flap to the end, is, I think the best sequence to follow, and the deferment of the dissection of the medial flap, which I have employed for the last 2½ years, by the reduction in haemorrhage which it entails undoubtedly leads to improvement in the post-operative condition of patients.

There are two points, however, on which I would like to comment.

(1) It is an axiom of surgery that an incision should be planned to give as direct access as possible to the area which has to be dissected, and it will be noted that in Wakeley's description of the operation the skin incision and the line of dissection of the axilla and the side of the chest cross each other. The incision which I now prefer is one which starts horizontally over the cleft between the clavicular and costal heads of the pectoralis major. As this incision approaches the anterior fold of the axilla it is made to curve downwards towards the tumour, which it skirts in a curve on its lateral side before passing on to the epigastrium. The horizontal part of the incision overlying the axilla and anterior axillary fold is deepened from the medial end laterally to expose the subscapular vessels, and this can be done with very little undermining of skin and therefore, with diminished bleeding.

I think it is quite unnecessary to divide the pectoralis close to the humerus, as recurrences do not occur in this area and dividing the muscle an inch or more from its insertion avoids unnecessary dissection of the skin. When the axilla has been cleared the vertical portion of the incision is deepened and the dissection proceeded with as described by Wakeley until the breast and muscle have been separated from the chest wall. A curved incision is then made in the skin medial to the tumour, completing the usual ellipse the medial flap is freed,

and the specimen removed. The resulting scar is, in my opinion, less objectionable than the usual orthodox one. This incision is applicable to the great bulk of cases, but it is not suitable for those growths which are placed well towards the medial margin of the gland.

(2) There is no doubt that interference with the ability of the patient to raise the arm above the head after operation depends mainly, if not entirely, on the level at which the lateral flap becomes adherent to the chest wall. This flap is raised when the arm is vertical but it is intolerable to the patient to attempt to keep the arm in this position during convalescence. The result is that in spite of any padding that may be employed in the axilla the lateral flap tends to slide down and though the patient may be able to raise the arm well during the first day or two after the operation, at the end of a week the flap will have become partly fixed and vertical abduction will be to some extent restricted. This slipping of the flap downwards can be obviated by the insertion of two or three catgut stitches between the deep surface of the flap and the upper intercostal spaces—a procedure which also obliterates dead space and reduces drainage to a minimum. If, as in some cases, it is found difficult to get a hold on the deep surface of the flap with the stitches, then silk stitches can be inserted in the intercostal muscles, their ends being brought out through separate punctures in the skin and tied over small gauze swabs.

I believe this refinement of technique helps considerably to avoid restriction of movement after operation—I am, etc.,

Birmingham 16

J W RIDDOCH

### Vagotomy

SIR,—I beg to question two important statements in the annotation entitled "Reports on Vagotomy" (Oct 2, p 652). It is stated that Vanzant found a late return to normal of gastric acidity after vagotomy in dogs. The reference given is to a publication of Vanzant's of 1932 which dealt with only three dogs.

In 1947 she published<sup>1</sup> the results of her more prolonged experiments with ten dogs, from which she came to these conclusions: that the acid response to a meat meal, though reduced at first, recovers to some extent after a few months and then falls again, and that the acid response to histamine becomes greatly reduced and shows no recovery at all. Since the response to a meat meal is believed to be at least mainly hormonal in origin it was surprising that vagotomy had any effect upon it whatever. Vanzant showed that it was due to a reduced reactivity of the gastric mucosa.

The operation of vagal resection in man is aimed at the all-important resting secretion, and this Vanzant did not investigate in her dogs. In Orr's and my series<sup>2</sup> of vagotomies started nearly four years ago and now numbering over a hundred we have repeatedly found continued depression of the histamine response as well as of the spontaneous resting secretion, nor have we found any return of the totally abolished insulin response.

It is also stated in the annotation that there have been several reports of patients dying from a painless perforation after section of the vagi. I know of reports where this has occurred after both vagotomy and thoraco-lumbar sympathectomy combined, the sympathectomy being almost certainly responsible for the anaesthesia of the peritoneum and possibly also for the flare-up of the ulcer. I can trace no publication recording painless perforation after vagotomy alone, and would be grateful for the references not given in the annotation—I am, etc.,

London W 1

H DAINTREE JOHNSON

\* Mr Daintree Johnson correctly summarizes Vanzant's conclusions after her more prolonged experiments, but it is worth noting that motility returned almost to normal in seven out of ten dogs. In humans Moore and others (*J Amer med Ass* 1947 133 741) also found that fasting acidity and motility returned to normal or almost normal by the end of one year. Alvarez in the paper quoted in the annotation mentions painless perforations and an account of a case is given by Walters and others (*Arch Surg Chicago* 1947, 55, 151)—ED B.M.J.

### Reactions to Intravenous Sclerotics

SIR,—I have read the comments of Dr R E Sidebotham (Oct 2 p 661) on my report (Sept 18, p 573) of two cases of acute allergy following intravenous injections of sodium morrhuate. I feel that Dr Sidebotham has missed the point of my letter, which was not to add two more descriptions of allergy to the list but to point out (1) the acquisition of an allergic state after a long period of time during which several injections were given—in the first case after the 16th injection and in the second case after the 25th injection—and (2) a repetition, in my second case, of an allergic reaction after changing to a completely dissimilar chemical substance.

I have used monoethanolamine oleate on a number of occasions and have found the sclerosing reaction so unreliable that I abandoned it several years ago. I think I have used most of the intravenous sclerotics, but I have never found that any of them approach sodium morrhuate in reliability for giving satisfactory occlusion. One important point in the technique is to get the assistant to maintain digital pressure for 5–10 minutes at the point of puncture immediately after the injection is made, this gives the sclerosing agent time to act before it is swept along the vein.

My view is that most cases of collapse with intravenous sclerotics which one sees occasionally are not true allergic cases, for in them there is no urticaria and no oedema of mucous membranes. My own observation of them is that they are of psychological origin and are caused by (1) using the standing position (the best), (2) the necessarily slow and deliberate nature of the injection, sometimes involving subcutaneous "seeking" of the vein and puncture of subcutaneous nerves, and (3) the use of ether or other odorous liquid as a skin cleanser. I have noticed that what few such collapses I have had have been at the patient's first attendance.

One must not minimize the extreme severity which psychological collapse can assume. The worst case of psychological shock which I have ever seen occurred while I was injecting varicose veins but in this case the reaction occurred in the husband and not the patient—I am, etc.,

Parley Surrey

C E TAYLOR

### National Hearing-aid

SIR—The contentions put forward by Mr A Edwin Stevens, Governing Director of Amplivox, Ltd (March 27, p 619), are almost exactly those advanced in New Zealand by commercial vendors of hearing aids when the New Zealand Department of Health's scheme was first mooted. The claims made have been disposed of completely in New Zealand by hard facts.

To those with a knowledge of the incidence of deafness in the various countries of the world the only criticism possible of the United Kingdom Government's estimate of the number of people likely to need instrumental assistance is that it is rather on the low side. American and New Zealand data disclose a higher percentage of the population in need of aids.

That the vast majority of deaf people have not seen a hearing aid is probably true. The high retail cost of aids is responsible for this. It is unreasonable to expect people to be familiar with objects that in the past have been so completely beyond their reach. That there is no widespread aversion to the use of aids is proved by the flood of applications received by New Zealand Hospital Hearing aid Clinics immediately the availability of hearing aids under the Social Security Benefit was made known to the public. Each release of New Zealand Government "Universal" aids results in an increased number of applications as the aids are shown to friends and relatives also in need of them. The New Zealand experience may reasonably be used to anticipate English experience, for the New Zealand "Universal" aid closely resembles that to be provided by the British Ministry of Health. Prototype aids built to the English specification and with the recommended components disclose almost identical performance.

High standards in mass production are a matter of efficiency of inspection. In any case there is hardly an aid in commercial production in the world to-day that is not more or less mass produced. Contrary to the opinion of Mr Stevens there is a standard aid suitable for the great majority of cases of hearing loss. This has been proved beyond doubt by the investigations made at the Harvard laboratories, U.S.A. as well as the comprehensive investigations made by the special committee in England. If further proof were necessary

it is provided by New Zealand experience in the issue of some 1,500 aids and the results secured from their use. The English committee refers in its Report No 261, *Hearing Aids and Audiometers*, to the need for special aids in a minority of cases. Such special model aids are in any case not provided at present by commercial interests. New Zealand experience shows that bone conduction aids are rarely of benefit, apart from those necessary in middle ear suppuration.

The successful use of an aid certainly depends on a number of factors, as stated by Mr Stevens. These factors are age, education, period of existence of the handicap, and its type and degree. These factors operate regardless of whether a mass produced high-price commercial aid is used or one issued by the Ministry of Health.

Report No 261 does not "admit the unreliability of crystal receivers" as claimed by Mr Stevens. It states, "They are liable to have a short life as a result of excessive forces which are applied to the crystal." The design of the English committee's aid is such that excessive forces are not applied to the crystal. It would appear that the limited use by English manufacturers of crystal receivers has in some cases prevented their appreciation of design requirements. This is indicated from a technical examination of several different English post-war models using crystal receivers. In one model there was no provision for limiting the aid output. At full volume-control setting loud speech or noise generated an output voltage of nearly 40 volts, R.M.S. The effect of this on both the crystal and the user's ear is obvious. In another model the receiver was connected directly across the choke. The cost of an output condenser was saved, but when the choke was burnt out, as sooner or later it would, by electrolytic action arising because no provision had been made to disconnect the "B" voltage when the aid was not in use, the receiver would also be destroyed. In a third model examined the output condenser used was of insufficiently high quality. Current leakage present would sooner or later destroy the receiver. The crystal direct-insertion type of receiver has been used in many thousands of aids in New Zealand over a period up to twelve years. The records disclose that failures are extremely rare, and those that do fail usually may be traced to mechanical damage following careless handling. Their outstanding advantages of extremely light weight, small size, and high sensitivity make them particularly suitable for use with hearing aids, but of course they are more expensive than magnetic receivers.

There has been no reaction against the use of hospital hearing aids clinics in New Zealand. On the contrary, there is widespread and warmly worded appreciation of the facilities provided. The charity atmosphere has been entirely removed from New Zealand hospitals.

Commercial hearing-aid vendors throughout the world have long claimed that the reason for the tremendous difference between the actual cost of aids (in the vicinity of £6 to £7) and their retail price (from £30 to £78) was due to the cost of the extensive after sales service they had to provide. The hard-of-hearing have just as persistently claimed that vendors have enjoyed their great margins of profit without in the vast majority of cases making any effort to provide adequate after-sales service. Mr Stevens will no doubt be consoled by the thought that the public is the best judge of the service it receives or has received, and if that afforded in the past by commercial vendors is as good as claimed then commercial vendors may confidently anticipate at least a share of the business of the hard-of-hearing when the distribution of free aids begins.

It is true that an alternative to the free Government aid is provided in New Zealand by means of a £15 subsidy on approved commercial aids provided they bear and comply with the New Zealand Standard Mark. It is significant that less than 10% of applicants seek the subsidy rather than the free aid. The many pathetic letters from victims of high-pressure unscrupulous salesmen and meretricious advertisements caused the New Zealand League for the Hard of Hearing to press for protection for purchasers. The League has very little sympathy for some vendors whose oncoming elimination will be the result of their lightly restrained greed—I am, etc.,

#### Use and Abuse of Tonsillectomy

SIR—I would like to say from the general practitioner's point of view how sincerely I agree with the letter from Messrs D F A Neilson and G H Bateman (Oct 2, p 660). There are times when I feel that there is almost no more useful purpose to which a hospital bed can be put than for Ts and As in properly selected cases. Further, I can see no justification for

the theory that the operation should not be performed in winter, it is true that it should not be performed on children with colds, and if hospital staffs are watchful it very seldom is, but I have never encountered any real ill effects from doing the operation in the winter. After all, the worst of the common catarrhal infections of childhood, measles, is often more prevalent in summer than winter, and so, if there is anything in this theory, would it not be safer to restrict the operation to the six weeks or so between the "flu" and measles seasons? In this connexion it is worth remembering the recent poliomyelitis outbreak, in which tonsillectomy virtually ceased against the better judgment of many surgeons. A few cases of poliomyelitis may have been prevented in areas where it was prevalent, but in this town the waiting list for tonsillectomy rose from about 50 to about 500, and the length of wait from a week or two to nine months, which in my opinion has been responsible for a great deal of unnecessary morbidity—I am, etc.,

J N FELL

#### Trilene as an Analgesic

SIR,—I should like to thank Dr C Langton Hewer and Professor R R Macintosh for their replies (Oct 9, p 691) to my letter (Sept 25, p 620) and for their assurance that the matter is under "active consideration." This expression, however, has a depressing familiarity about it and will bring little comfort to the many thousands of patients who remain unrelieved in labour to a degree quite unjustified in these modern times.

Professor Macintosh refers to the unconscious patient. I do not believe that it is possible under the conditions specified for loss of consciousness to be produced in any patient no matter what the individual susceptibility, the depth of respiration, or the room temperature may be. Short of complicated tricks, difficult to arrange such as placing the inhaler in hot water maliciously overfilling it, etc., such a risk is non-existent. At all events it is very much easier, by accidental or unfair means, to produce a dangerous situation with gas-and-air machines than with a "trilene" inhaler. I have seen it occur more than once. The risks of gas-and-air analgesia in the hands of midwives were for long exaggerated and the difficulties thought insuperable, but both were quickly overcome directly practical action began.

Discussion of this subject could be endless so I must content myself with making my plea for a much more sympathetic attitude to these cinderellas of medicine, largely forgotten and left with precious little aid or attention in this respect. More sympathy and more personal experience of the actual conditions which exist would lead to greater activity and quicker results and would go far to remove what is I believe, the one remaining blot on the escutcheon of British obstetricians—I am, etc.,

London W 1

F NEON REYNOLDS

#### Fibrositis

SIR—Dr I H Milner (Oct 9, p 691) complains that my letter (Sept 25, p 617) "adds very little clarity" to the article of Dr James Cyriax (July 31, p 251). I am glad to say that this is due to a misunderstanding. My letter contains in the main two points.

(1) A statement of facts. *non-articular rheumatism* is for practical purposes due to and caused by a "myalgia" defined as a muscular disease characterized by the well known subjective symptoms and by objectively localizable "myalgic spots" which can be ascertained in anatomical points of a muscle—viz, origin insertion, the border or its course and its tendon ligaments etc. The diagnosis has to be made *not* by "tender spots" which are purely subjective but by objective criteria independently of patients' complaints. Appropriate injections of procaine relieve the complaints and lead to a rapid cure.

(2) I have put forward the hypothesis that myalgia is a functional disease the dynamic pathology of which can best be explained by a deficient circulation in the "myalgic spots," the root of the disease. The deficient circulation leading to a relative oxygen want (hypoxia) is brought about by a relatively diminished blood flow defined as the quantity of blood passing through a unit of tissue per minute. The latter might be caused either by vasoconstriction (sympatheticotonia) or by

vasodilatation leading to a stasis of the blood in the capillaries. The latter mechanism of pain, the leading symptom of myalgia, is for instance responsible for inflammatory pain. The details will be given in a paper, 'A General Theory of Pain, which I hope will be published in the near future—I am, etc.

London N W 11

M G GOOD

### Surface Phagocytosis

SIR,—The fact that you make no mention in your interesting review (Oct 9, p 687) of the work of W Barry Wood and his colleagues of certain other activities of leucocytes suggests that these may not be as well known as they should be. Leucocytes in fluids such as urine and sputum are often seen to send out pseudopodia around objects encountered, such as epithelial cells. That this activity is not engendered by anything specific to the epithelial cell is shown by precisely similar behaviour if a leucocyte comes in contact with an air bubble, long pseudopodia run out round the bubble. It would be interesting to see whether bubbles of an inert gas would elicit the same response.

The phagocytosis of bacteria in such fluids is evidently a complicated phenomenon. In urine a substance can sometimes be seen streaming from the surface of the leucocytes to which motile bacilli stick in huge numbers. On other occasions, and particularly with non motile bacteria such as streptococci, classical amoeboid phagocytosis usually takes place. The phagocytosis of large numbers of dead and moribund cells occurs in a rather different way by means of long filopodia surrounding the masses, usually numerous leucocytes co-operating.

The approach by Wood in an attempt to distinguish the leucocytic and humoral factors seems most promising—I am, etc.,

Cirencester Glos

R E HOPE SIMPSON

### Teaching Occupational Medicine

SIR,—I would like to endorse Dr Richard Schilling's remarks (Oct 9, p 694) with reference to the teaching of occupational medicine. One of the difficulties of planning a course of studies in this subject is that all those taking it are probably destined to work in widely different fields and require different specialized knowledge.

While the basic principles of, for example, environmental control, placement of workers, rehabilitation of the sick and injured, maintenance of records, and the aetiology of specific occupational disease remain constant and can and should be included in any course of instruction, the infinite variety of environment and hazards which occur in different industries makes it quite impossible to provide detailed teaching on them all. Nevertheless it is desirable that the possession of a D.I.H. should reflect a competent knowledge of the more important health hazards of the working environment from which the budding industrial medical officer can take off into the toxicological and other ramifications of his own industry.

Industrial law is a difficult subject to teach and make interesting to the average student. At the same time, if it is taught at all it must be taught in detail otherwise it is worse than useless. The difficulty again is to know where to draw the line. Finally I quite agree with Dr Schilling that the D.P.H. and D.I.H. courses are capable of far more amalgamation than exists at present. This would undoubtedly benefit both pupils and teachers—I am, etc.,

Edinburgh

CATHERINE SWANSTON

### Resuscitation by Rocking

SIR,—Referring to the article by Dr F C Eve and the late Dr N C Forsyth (Sept 18, p 554) I am sure that all will agree that Dr Eve has done a great service in emphasizing the value of rocking in the treatment of asphyxia neonatorum and in calling attention to the too frequent "quiescent" treatment of shock. But in my opinion bias in favour of one particular method of treatment should be avoided for fear of overlooking other useful methods.

Long before Dr Eve gave to this country the life saving rocking stretcher I saw "Mother Gamp" rocking a lifeless baby and splashing its body with cold water. She didn't know the value of the diaphragm in enlarging the capacity of the

thorax or anything about the reflex action of the cutaneous nerves, but I have heard her say, 'It's all right, it's colours coming'.

In my opinion it is wrong for Dr Eve to compare the resuscitation of a drowned boy of 14, or of two adults seriously injured, with a child which has never breathed. When he suggests, "Take care of the circulation and leave respiration to take care of itself," he is slashing at established teaching and reopening the acidosis argument which Professor Yandell Henderson and others so completely closed.

Frequently in the good old days rocking had to be helped by mouth-to-mouth inflation with 4% (or more) of my own CO<sub>2</sub>, but since 1932 I have carried a supply and often used a concentrated CO<sub>2</sub>. In the last score of newborn asphyxias this treatment has given complete success and I have had no fatalities. Moreover, some of my babies which caused no anxiety at birth but failed to cry lustily during the first few days have been given a whiff of concentrated CO<sub>2</sub> in order to avoid any area of atelectasis. I have invariably seen excellent results. Thus my long experience goes to disprove Dr Eve's claim that 7% CO<sub>2</sub> is a deplorable poison—I am, etc.,

Hemel Hempstead Herts

GILBERT BURNET

### Scope of Geriatrics

SIR,—I see in your columns an advertisement for a "geriatric specialist" to be in charge of the chronic-sick wards of a hospital. May I suggest that geriatrics, which is the care of the aged, is not quite synonymous with charge of the chronic sick? Old people are often acutely ill with such diseases as bronchopneumonia, coronary thrombosis, infections of the urinary tract, and so on. Some of the chronic sick are definitely not in the senile age group and are really untreatable disorders in relatively young folk. Success in the practice of geriatrics is measured by the prevention of serious crippling disease and by no other yardstick. This calls for therapeutic activity in the homes of old people, in out-patient clinics and in physiotherapy departments more than in "long term" hospital wards. Unless this distinction is made clear now, the newborn babe of geriatric medicine is likely to be smothered during its tender infancy—I am, etc.,

Parley Surrey

TREVOR H HOWELL

### Hospital Admissions and Records

SIR,—I would like to draw the attention of your readers to a report of the King Edward's Hospital Fund entitled, *Some Observations on Hospital Admissions and Records*. This report which represents the opinions of a group of administrators, will be welcomed by records officers because it recommends the adoption of principles for which those actually engaged in hospital record keeping have been striving for a long while. The most important implication is perhaps the implicit recognition that the job of records officer is a reality. It was, indeed in order to achieve just such an improvement in the standard of medical records which this report urges that records officers up and down the country have formed an Association of Medical Records Officers. Records officers have, in fact, begun to put their own house in order by pooling their experience and by making arrangements for the more highly trained to provide educational courses for those who are not in touch with modern techniques and for new entrants to the service. Their efforts will receive impetus from the encouragement which this report gives.

The recommendation that the hospital should have a records committee elected by the medical committee from among its members and including the chief administrative officer of the hospital and a representative of the nursing staff in order to lay down a policy with regard to records, if universally adopted will greatly facilitate the work of the lay records officer by encouraging co-operation from all members of the staff and providing a channel through which each member of the hospital team can acquaint other members with special difficulties.

The committee comments that there is at present no recognized training for records officers and urges that some regularized course should be agreed upon. An interim course has in fact been worked out by the Association of Medical Records Officers and a beginning has already been made with weekend lecture courses at teaching hospitals at Bristol, London

## INCREASED PREVALENCE OF HYPERACIDITY

One legacy of war-time strain persists. It is evidenced by the number of patients exhibiting symptoms of gastro intestinal disorder.

The same stress factors of overwork, hurried, irregular meals and the inability to relax completely still prevail.

In such instances, 'Milk of Magnesia' is invaluable in securing rapid control of discomfort. A colloidal suspension of magnesium hydroxide, it soothes the inflamed mucosa, and neutralizes the excess acid, without liberation of gas. Furthermore, its mild laxative action ensures removal of toxic waste products.

'Milk of Magnesia' may be prescribed with confidence equally in the mild case of dyspepsia or the acute ulcer stage where sustained alkaline treatment is essential.

#### OPTULLE (TULLE GRAS)

A wide mesh gauze impregnated with Balsam of Peru in a Petroleum Jelly base. Recommended as a dressing for burns, scalds, cuts and abrasions. OPTULLE is of particular value in the treatment of sores and indolent ulcers and, in that it protects, stimulates and permits drainage of exudates, facilitates healing when used for sore patches of impetigo, eczemas and similar skin troubles. It has also been found a most satisfactory preparation for the dressing of skin grafts, and in plastic surgery. OPTULLE is non-adherent and allows a change of dressing without destroying fragile healing tissues. OPTULLE is completely safe in the hands of patients.

**MEDICAL PRICES** 24 dressings 4" sq. (approx.) 4/- per tin 45/- per doz.  
Continuous strip 5 yds x 8" 9/- per tin.

#### SULPHONA-TULLE

An open mesh gauze impregnated with an emulsion containing 10% Sulphanilamide. Recommended as a dressing for wounds and burns whether sterile or infected. SULPHONA-TULLE is also of great value in the treatment of most septic skin conditions, chronic ulcerations, indolent ulcers, pruritus, intertrigo, etc.

**MEDICAL PRICES**  
In a compact tin containing a strip 5 yds x 3½" 6/- per tin or 66/- per doz.

#### SULPHONA-CREAM

A cream containing 10% w/w Sulphanilamide in Paraffin-Lanolin-Water emulsion. A useful adjunct to Sulphona-Tulle particularly suitable for use by the patient in carrying out, in the home, the treatment prescribed by the doctor.

**MEDICAL PRICES** : ½ oz. tubes 13/6 per doz. 1 lb. jars - 13/6 each. The printed labels to the tubes are detachable leaving space for the Doctor's own advice to be written.

MANUFACTURED BY

**Optrex Ltd.**

PERIVALE, MIDDLESEX

Price to hospitals on application to sole distributors **CHAS. F. THACKRAY LTD**  
10 PARK STREET LEEDS 1 and 39 WELBECK STREET LONDON W.1

## 'PERNIVIT'

*Tablets of Acetomenaphthone  
and Nicotinic Acid B D H*

Considerable success in the treatment of chilblains has been reported following the use of acetomenaphthone in one group of patients and of nicotinic acid in a second group.

It may be that abnormal venous permeability and prolonged blood clotting time on one hand and venous stasis from vasoconstriction on the other may both be contributory causes of chilblains.

Trial of a combination of acetomenaphthone and nicotinic acid collaterally, therefore, seems justified. 'Pernivit' is now available as tablets, each containing

Acetomenaphthone	7 mg
(Prokayvit Oral)	
Nicotinic Acid	25 mg
Bottles of 50 and 500 tablets	

MEDICAL DEPARTMENT  
THE BRITISH DRUG HOUSES LTD LONDON N.1

Prvt/E/020

Manchester, Cardiff, and Sheffield, with further courses to come at Leeds, Newcastle, and other centres. At these courses to which hospitals within the appropriate regions are invited to send records staff, lectures and demonstrations are given on the following subjects: hospital organization, office management and selection of staff, appointments system, registration, admission, and discharge procedure, case history routine, follow-up systems, forms, filing methods, indices, office equipment, and paper control, diagnostic nomenclature, hospital statistics. At these lectures standard principles on which progressive records officers have agreed are universally followed. It is hoped later to organize full-time training.

A full comment on the King's Fund report would encroach too much upon space. It has been sent to the committee and will be published in the next A M R O bulletin—I am, etc.,

B. BENJAMIN,

London S E 1

Chairman Association of Medical Records Officers

## POINTS FROM LETTERS

### Professional Nomenclature

Mr T. W. LETCHWORTH (London, W 1) writes: Though not a classical student, might I be allowed to add a word to Dr A. Barnsley's protest (Aug 28, p 440) against our appalling professional nomenclature? As a student I remember jeering at the French for coining such a hybrid as *calorimeter*, but what do we see now? I fear that most of these abominations are too far rooted for any hope of extermination. We have *venereology* for *aphroditology*, *appendicitis* for *epityphlitis*, *audiometer* for *acuometer*, and, worse than all, *caecostomy*. *Stoma* is wrong, because it is not a mouth. Contrariwise, if you will stick to *stoma* the word should be *typhlostomy*. Is there no authority that can stop this desecration of our language? Scarcely a new name is coined but it needs be a mongrel!

### Treatment of *Lamblia* Intestinalis

Dr K. D. LOUFFY (Alexandria) writes: The manifestations of *Lamblia* infection are diarrhoea and intestinal colics, with occasional symptoms simulating chronic cholecystitis such as flatulent dyspepsia, and occasional mild biliary colics. The *Lamblia* inhabits the upper intestinal tract, duodenum, jejunum, and gall-bladder with its bile ducts. The latter may harbour the parasite and make it resistant to treatment. Mepacrine is usually given in divided doses of 0.1 g three times daily after meals for five days. With this routine the *Lamblia* infection usually recurs and resists the treatment in 90% of the cases. The other routine is to give to the patient in the early morning magnesium sulphate to empty the gall bladder and its ducts and follow this a quarter of an hour later by 0.3 g of mepacrine in one dose for an adult on one day only. This is repeated after one week. I have treated thirty cases by this routine in two years without relapses. Of these thirty cases twenty had been previously treated by the old method of divided doses and had relapsed.

### Anatomy of the Primates

Dr A. M. FRASER (Birkenhead) writes: My knowledge of the anatomy of the primates is very limited, but the article by Professor F. Wood Jones (Oct 2, p 629) on the unsatisfactory present state of our knowledge of this subject dismays me, as it leaves me in the air as to what is meant. Most of the article is occupied with disproving the grounds of Darwin's guarantee that man had evolved from an ape-like progenitor, but no alternative idea is put forward other than further study of the primates. Study for what purpose? For proving Darwin's confident assertion of man's ape-like progenitor?—but that was done 77 years ago. For disproving it?—no real alternative is suggested in the article. For a definition more accurate than 'ape-like'?—but is the time and trouble justifiable these days? Animal, vegetable, and mineral are well-defined groups of the present world, but consideration of the principle of borderline cases (crystalline viruses is an example that comes to mind) indicates to me that the connecting similarities are more important than the differences for the understanding of the whole. There is obviously a steady step-by-step progression from the simple atom to complex man.

Dr Robert Cruckshank, director of the Central Public Health Laboratory Services, left Britain on Oct 16 for a short lecture tour in the Netherlands under the auspices of the British Council. He will be speaking in Amsterdam, Rotterdam and Utrecht on various problems connected with the control of infectious diseases. He will then deliver a lecture at Brussels on the diagnosis and control of whooping-cough, a subject which has been specially chosen because much of the pioneer work on the control of the disease was done in Belgium earlier this century.

## Obituary

SUSAN ISAACS, C B E, D Sc

Dr Susan Isaacs died at her home in London at the age of 63 on Oct 11. She had suffered her long illness with great courage, working on her publications almost to the end. Susan Isaacs brought to the study of children and child psychology the unusual combination of sympathetic insight and rigorous scientific thinking. These, together with a facility of expression in both the spoken and written word, gave her an international reputation and led to her great influence on current methods of handling children.

Trained originally in philosophy under Professor S. Alexander at Manchester, Mrs Isaacs became a lecturer in logic and later an academic psychologist. This role, however, did not satisfy her, and, when Geoffrey Pyke in the nineteen-twenties set up the Maltng House School in Cambridge, Susan Isaacs welcomed his invitation to join the staff. This opportunity for the study of the spontaneous interests and behaviour of young children in a comparatively free atmosphere was not missed. Detailed records were kept and formed the basis for her two classical works on child development: *Intellectual Growth in Young Children* (1930) and *The Social Development of Young Children* (1933). The combination of observed data and theoretical discussion was unique at that time. Psycho-analysis had for long been appreciated by Susan Isaacs as the most fruitful approach to the study of personality, and after leaving the Maltng House School she trained as a psychoanalyst in London. Specializing in child analysis, she became closely associated with Melanie Klein, whose views she helped to develop and clarify. As was to be expected, Mrs Isaacs took a leading part in the work of the London Institute of Psycho-analysis and contributed many scientific papers. She was active in the reorganization of the Institute after the war, was on the teaching staff and served on both the training committee and the council. Because of her practice as a lay analyst she was diffident about using the title of doctor, to which she was entitled by her D Sc taken in 1931.

Despite her increasing absorption in psycho-analysis Mrs Isaacs continued active work in the educational sphere. From 1933 to 1939 she was in charge of the Department of Child Development in the Institute of Education of London University, and from this key position had a profound influence on the development of nursery school work in this and other countries. Senior and promising workers from the nursery schools began to take the course and to have taken it soon became a valuable qualification for those seeking posts on the staffs of training colleges. The existence of this department and of Susan Isaacs at its head was a great opportunity for the University to develop a research centre in child development such as exist in many universities in the United States. For various reasons this opportunity was missed and Britain still lacks a flourishing university school in child psychology which Susan Isaacs's distinction and ability could so easily have developed. Educational theory and practice and psycho-analysis by no means absorbed all Susan Isaacs's great energy and capacity for work. Her deep concern for the welfare of children led her to play a leading part in the nursery school movement, in the survey of evacuated children undertaken by a group in Cambridge in the first year of the war and in the Press campaign which led to the appointment of the Curtis Committee. The findings of the Cambridge Evacuation Survey were published under her editorship in 1941, whilst her detailed and well-documented evidence put before the Curtis Committee was republished in a recent and valuable collection of her technical papers *Childhood and After*.

Susan Isaacs was remarkable for her mastery of so many aspects of her subject. She was equally at home in educational and psychological theory, in both of which she was deeply read in the practical day-to-day management of children, and in the therapy of patients of all ages. She had the capacity, moreover, for popular exposition both in lecture form and in articles and booklets. *The Nursery Years* published in 1929 at once established itself as a standard manual on child psychology and child care whilst one of her last tasks was to select for republication only a month ago her answers

mothers questions published weekly for some years in the *Nursery World*. With all this she found time for the pleasures of music and an active social life amongst a wide circle of friends. Always modest and approachable, she wore her erudition lightly and was unstinting in her help of colleagues and students.

Mrs Isaacs was the youngest of a large family. She was married twice, first to W B Brierley (her first books were published under the name of Susan Brierley) and secondly to Nathan Isaacs. She had no children. She was made an honorary DSc of Adelaide University, and in the recent New Year's Honours was appointed CBE.

### J W S MACFIE, DSc, MB, DTM

Dr J W S Macfie who had a long and distinguished career in the Colonial Medical Service and was well known as a malarialogist died at St Leonards on Oct 11 at the age of 69. John William Scott Macfie was born at New Ferry, Cheshire, and educated at Oundle, and subsequently at Cambridge and Edinburgh University, where he graduated MB ChB in 1906. After a period in the physiology laboratory at Liverpool under Sherrington Macfie's interests turned to tropical medicine. He took the diploma in tropical medicine at Liverpool in 1910 before going out to Africa and joining the West African Medical Staff. He served in North and South Nigeria and on the Gold Coast, and from 1914 to 1923 he was director of the Medical Research Institute at Accra. During this time Macfie was responsible for much original work on a number of tropical diseases, particularly trypanosomiasis and malaria. In 1917 he was seconded to the Liverpool School of Tropical Medicine to undertake special research on malaria. Two years later he was awarded the Mary Kingsley Medal of this School for his outstanding work in the field of tropical medicine.

Dr Macfie on returning from West Africa, joined the staff of the Liverpool School of Tropical Medicine as lecturer in protozoology. In 1927 he started work on the chemotherapy of malaria, under the aegis of the Medical Research Council, at the London School of Tropical Medicine. In spite of failing health he volunteered for service in Ethiopia in 1935 as second in command of the British Red Cross Unit serving there. His book, *An Ethiopian Diary* was published in the following year. Thereafter he was engaged temporarily in medical activities in London, but in 1941 at his insistent request he was appointed a temporary major in the R A M C. He served with distinction in No 3 and No 8 Malaria Field Laboratories in Egypt and Syria and elsewhere in the Middle East as a malarialogist. Returning to this country after a breakdown in health, he relinquished his commission in 1943 and renewed his old interest in taxonomic studies at the British Museum. Macfie also returned for a short time to the Liverpool School, where he was engaged in the preparation of an instructional film on malaria.

Macfie was a worker of eminence and erudition in many branches of tropical medicine. He was a world authority on the midges (*Ceratopogonidae*) and was largely responsible for the identification and classification of the collection of these insects in the British Museum. Macfie's kindness unassuming men and tall ascetic figure endeared him equally to his contemporaries and to his junior colleagues many of whom will recall with gratitude his unostentatious benefactions.

## Universities and Colleges

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

A series of postgraduate lectures in general medicine will be given at the College (Pall Mall East S.W.) on various dates between Nov 2 and Dec 17 at 5 p.m. each day. The inclusive fee for the course is £7 7s and the total entry is limited to 200. Fees are payable in advance and must be received at the College by Oct 25.

### ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

A postgraduate course of advanced lectures for those studying the special practice of obstetrics and gynaecology will be given in the College House (58 Queen Anne Street London, W) from Monday

Nov 15, to Friday, Nov 19, inclusive, at 12 noon and 5 p.m. each day. The fee for the course of ten lectures is £4 4s 10s 6d for a single lecture. There will be no admission without a ticket, obtainable from the secretary of the College.

At a special meeting of Council of the College, held at the College House on Oct 1, with the President, Sir William Gilliatt, in the chair, the Honorary Fellowship of the College was conferred on Dr Emil Novak, of Baltimore, U.S.A.

A F Hollinrake (Ontario) was admitted to the Fellowship. The following were admitted to the Membership:

I S R Bain Henrietta E Banting T L S Baynes S Behrman D C A Bevis C C Bowley T St V W Buss L W Cox Mary E Egerton T E Elliot G McI Forsyth H D Freeth G T Gibson J H Gibson A Graham A H Greoz Constance A Grey H B Hattam C C Henneberg E Hesselberg D W Higson J C Holman K R Hudson A G Jones J B Joyce W T Kenny G W Kerster R A H Kneeb S Lask T L T Lewis E L F McConnachie W Macfarlane J M McKiddie J R Madden Helen M Mayer G W H Millington F L E Musgrove J R Norris J J F O'Sullivan J H Patterson, A C Pearson W H Peel S D Perchard D Pryor Jones E H Rees S McReid H A Ripman D N S Robertson B W Saunderson G A Silley A A Smith T Smith G J Sophian Christos M Stacey P C Steptoe C S N Swan, R A Thatcher G S Thomas R G Whitelaw R M Williams M S Williamson H G Wolskel P S Wright R B Wright

## EPIDEMIOLOGICAL NOTES

### Discussion of Table

In *England and Wales* an increase was recorded in the notifications of measles 843 scarlet fever 166, acute pneumonia 125 acute poliomyelitis 13, and typhoid fever 11. Decreases were reported in the incidence of whooping cough 55 and dysentery 10.

The incidence of measles tended to rise throughout the country, but large increases were recorded in only a few counties, notably Yorkshire West Riding 318, Lancashire 210 Cheshire 58, and Derbyshire 50. A small rise in the notifications of scarlet fever was reported from most areas, the largest increase was 35 in Yorkshire West Riding.

The local trends of whooping cough fluctuated, the largest variations were a rise of 49 in Lancashire and a fall of 50 in Yorkshire West Riding. There was no appreciable change in the local returns of diphtheria. The rise in the incidence of pneumonia was mainly contributed by the West Midland and Yorkshire regions, and a rise of 39 was recorded in both regions.

The chief centres of dysentery were Lancashire 19 and London 12. A further 31 cases were notified in Shropshire Oswestry R.D. During the past four weeks 87 cases have been notified from this outbreak.

The largest returns of acute poliomyelitis were Yorkshire West Riding 8 (Sheffield CB 3) London 7 (Woolwich 2) Staffordshire 7 (Wolverhampton CB 3), Glamorganshire 7 (Swansea CB 3, Cardiff CB 2) Surrey 5 Gloucestershire 5 (Bristol CB 5), Warwickshire 5 (Birmingham CB 2).

In *Scotland* infectious diseases were more prevalent during the week and increases in the number of notifications were recorded for acute primary pneumonia 54, scarlet fever 33 diphtheria 17, and dysentery 10. The increased incidence of these diseases was mainly contributed by the city of Glasgow.

In *Eire* a rise of 28 occurred in the notifications of diarrhoea and enteritis, of this increase 20 cases were notified in Dublin CB. An outbreak of measles affecting 28 persons was notified in Clare, Kilmish R.D. Notifications of scarlet fever were 20 fewer in the large cities, but this was offset by a rise of 16 in the remainder of the country.

In *Northern Ireland* increases were recorded for measles 34 whooping cough 16 and scarlet fever 13. The rises in the incidence of the first two diseases were due to the experience of Belfast CB, while a small increase in the notifications of scarlet fever was fairly general throughout the country.

### Quarterly Returns for Northern Ireland

The birth rate during the second quarter was 23.9 per 1000 and was 0.9 below the average of the five preceding June quarters. The infant mortality was 44, and was 18 below the average of the corresponding quarters of the five preceding years. Maternal mortality was 1.1 per 1000 births, being 1.4 below the five years' average. The general death rate was 11.4 and was 1.0 below the average of the June quarters for 1943-7. Deaths attributed to the principal infectious diseases numbered 63, and included 30 from diarrhoea and enteritis and 13 from whooping cough. Deaths from pulmonary tuberculosis numbered 178 and from other forms of tuberculosis 81. These figures were 35 below and 2 above the five year average.

### Week Ending October 9

The notifications of infectious diseases in *England and Wales* during the week included scarlet fever 1,273, whooping-cough 2,073, diphtheria 112, measles 4,061, acute pneumonia 421, cerebrospinal fever 31, acute poliomyelitis 79, dysentery 84, paratyphoid 13 and typhoid 18.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct 2

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease, are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)

Rate per 1 000 total births (including stillbirths)	—	—	35	—	—	—	39	—	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales (London (administrative county) will no longer be published

‡ In the primary form for England and Wales (London (administrative county) and Northern Ireland

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales (London (administrative county) are combined

¶ Includes puerperal fever for England and Wales and Eire

## Special Awards Committee

The Government has decided to set up the Special Awards Committee recommended by the Spens Committee for selecting those specialists whose outstanding distinction merits higher financial rewards than the ordinary rates. The constitution of the committee has been settled after consulting the Royal Colleges and the Scottish Royal Corporations. Invitations to the individual members will be issued shortly.

## King Edward VII Hospital for Officers

Her Majesty Queen Mary opened the King Edward VII Hospital for Officers on Oct 15. The hospital was founded by Sister Agnes in 1899 in her own house at 17, Grosvenor Crescent, and in 1945, after having been closed as the result of bombing in 1941, was moved to its present site Beaumont House, Beaumont Street, London, W1. There are two wards of five beds and two of two beds where nursing and maintenance are free, and seventeen single rooms for which low fees are charged. Patients make their own arrangements with their medical attendants. Regular and retired officers of the Royal Navy, the Army, and the R.A.F. are eligible for admission, as well as temporary officers of the three Services who fought in the two world wars provided they become subscribers. The annual subscription is £1. Particulars may be obtained from the house governor of the hospital.

## Society of Anaesthetists

A meeting of seventy anaesthetists was held at Westminster Hospital on Saturday, Oct 2, and the Society of Anaesthetists of the South West Metropolitan Region was inaugurated. An invitation is extended to all anaesthetists in the region to join the society. Full particulars may be obtained from Dr W. Alexander Low, St Thomas's Hospital, S.E.1.

## Health Centres in London

The Minister of Health has approved the London County Council proposal for a comprehensive health centre on the Council's Woodberry Down estate, Stoke Newington, and for the acquisition of sites for other centres. The Minister points out that the Council will be responsible for providing, in the case of medical practitioners working at health centres all drugs and appliances required immediately or administered by the practitioner in person and all materials used in dental treatment and dentures. No objection is taken to the proposal to have a foot clinic at the Woodberry Down centre, but formal approval awaits the submission of a detailed scheme. It is the Council's intention to provide a health centre in each of the nine divisions of the county, this will be carried out by converting existing buildings, and detailed proposals in respect of each building will have to be submitted to the Minister and agreement obtained with the executive council. The Minister's approval in principle is given to the establishment of an unspecified number of group practices, but it will be necessary in each case to obtain the consent of a group of general practitioners to work in a group practice and for the executive council to agree to the establishment of such a group practice before full details of the scheme are submitted to the Minister for his approval.

## Nuffield Foundation

Among the grants made by the Nuffield Foundation and described in its recently issued third report is one of £20 000 to the London University Institute of Psychiatry (Professor Aubrey Lewis) for a ten-year investigation into the value of psychological tests of intelligence and personality. The tests will be applied to applicants for admission to certain universities successful and unsuccessful applicants will be followed up. One method of entry into the middle class is by university education, and this study of the selection of university students may throw some light on a problem to be the subject of another investigation—namely, the middle classes. The London School of Economics has been granted £20,000 to study this 'complicated caste system'. The Oxford University Medical School has been granted £50 000 to study the blood and the blood-forming organs. The sum of £4,000 has been granted for a survey (to be undertaken jointly by the Royal College of Obstetricians and Gynaecologists the Population Investigation Committee and the London University Institute of Child Health) of the health of all children born during one week in 1946. The trustees of the Fund record that they have received a gift of £450,000 from Captain Oliver Bird for the promotion of research into the prevention and cure of rheumatism.

## Wills

Dr Edward Alfred Dingley, of Wednesbury Staffs left £41,156, and Mr John Daniel Harmer late of the Northern Rhodesia Medical Service, £1,413.

## COMING EVENTS

## Chemical Works Safety Conference

The Association of British Chemical Manufacturers has invited the Royal Society for the Prevention of Accidents to organize on its behalf a Chemical Works Safety Conference, which will take place at the Grand Hotel, Harrogate, on Oct 29 to 31. The opening address will be given on Oct 29 by Sir Ewart Smith, of Imperial Chemical Industries, Ltd, and the programme will include the following lectures: 'Health Hazards—Present and Future,' by Dr J Gwynne Morgan of the Mond Nickel Co., Ltd, "Safety in Chemical Plant Design," by Mr J E Braham, B.Sc., of ICI, Ltd, 'Safety Organization,' by Mr H R Payne chairman, Works Safety Committee, A.B.C.M. 'Safety Records,' by Mr H G Winbolt, B.A., director, Industrial Safety Division Royal Society for the Prevention of Accidents, 'Clearance Certificates,' by Mr A G Palmer, B.Sc., of the Gas Light and Coke Co.

## Prosser White Annual Oration

The St John's Hospital Dermatological Society announces that the Prosser White Annual Oration will be delivered by Dr J M H MacLeod at the Royal Society of Medicine (1, Wimpole Street, London, W) on Thursday, Oct 28, at 4.30 p.m. His subject is 'Milestones on a Dermatological Journey'. A dinner will be held the same evening, the tickets for which are £1 1s each, obtainable from the honorary secretary of the society, Dr J E Schneider Green, at 5, Lisle Street, Leicester Square, London, W.C.2

## St John Ambulance Brigade Surgeons' Annual Dinner and Conference

Arrangements have been made for this year's dinner and conference of the St John Ambulance Brigade Surgeons to be held at the Royal Hotel, Woburn Place, London, W.C., on Saturday and Sunday Oct 30 and 31. Mr Dickson Wright, Sir Ernest Rock, Caring, and Dr Frank C Eve will be among the speakers, with Lord Webb Johnson as the principal guest at the dinner.

## Anti vitamins in Food

The Nutrition Society has arranged a whole day conference to be held at the Royal Society of Arts, John Adam Street, London W.C., on Saturday, Oct 23, beginning at 10.30 a.m., when the subject for discussion will be "Anti vitamins in Food."

## Courses in Psychiatry

The University of London Institute of Psychiatry will hold courses for first year and second year students on psychology and psychiatry this autumn. The fee for one term's lectures is 15 guineas. Particulars may be obtained from the Dean, Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5 (Telephone Rodney 2634).

## Planning Forum

The following meetings of the Planning Forum, which is sponsored jointly by the Association for Planning and Regional Construction, the British Social Hygiene Council, the Institute of Public Administration, Political and Economic Planning (P.E.P.), and the Town and Country Planning Association, are announced: Wednesday, Oct 27, 6.15 p.m. discussion on the Kinsey Report on "Sexual Behaviour in the Human Male," to be opened by Dr David Mace, Ph.D., Dr Fred Grundy, and Dr E H Larkin, Thursday, Nov 11, 6.15 p.m., discussion on 'Population and Emigration,' to be opened by Professor Brinley Thomas, Ph.D., and Mr R J Goodman, Wednesday, Nov 24, 6.15 p.m., discussion on 'Work and Health' to be opened by Dr R S F Schilling, Mr Brian Bunch, and Dr John Burton, Thursday, Dec 9, 6.15 p.m., discussion on 'Manpower' to be opened by Mr A E U Maud and Mr G D N Worswick. The meetings will be held at the Planning Centre Hall, 28, King Street, Covent Garden, London, W.C. Admission to each is 1s.

## Medical Society of London

The first half of the 1948-9 session of the Medical Society of London opened at 11, Chandos Street, Cavendish Square, W, on Oct 11 with the annual general meeting and Dr T Jenner Hoskin's presidential address on thyrotoxicosis. Other meetings have been arranged as follows: Monday, Oct 25, 8.30 p.m., discussion on 'Streptomycin' to be introduced by Dr Jack Rubie and Dr Geoffrey Marshall, Monday, Nov 8, 8 p.m., pathological meeting, Monday, Nov 22, 8.30 p.m., discussion on 'Gastroscopy,' to be introduced by Dr Avery Jones and Mr Hermon Taylor, Monday, Dec 13, 8.30 p.m., discussion on 'Therapeutic Application of Anti coagulants' to be introduced by Dr Paul H Wood and Mr A Dickson Wright. The Lloyd Roberts Lecture, "Victorian Doctor" will be delivered by Mr J Johnston Abraham on Thursday, Nov 18, at 5 p.m. the Lettsomian Lectures by Dr Horace Evans on Monday, Feb 21 and 28 and March 7, 1949, at 9 p.m., and the Annual Oration by Mr A C Palmer on 'Temperament' on Monday, May 9, 1949, at 8.30 p.m.

## SOCIETIES AND LECTURES

## Saturday

ST STEPHEN'S HOSPITAL RHEUMATISM UNIT, 369 Fulham Road, London, S.W.—Oct 23, 10 a.m. *General Medicine in Relation to the Rheumatic Diseases* by Sir Adolphe Abrahams, 11 a.m. *Modern Conception of the Aetiology and Classification of the Chronic Rheumatic Diseases* by Dr Philip Ellman, 12 noon, *Organization of a Rheumatism Unit with Special Reference to the Management of Rheumatoid Arthritis* by Dr Francis Bach, 2 p.m., ward round and demonstration of methods of physical treatment, injection, and plaster technique by Dr Bach, 3 p.m. *Social Welfare Dietetics, Occupational Therapy and Vacation Guidance* by Dr Bach and members of the staff of the unit, 4.15 p.m., *Clinical Pathology in the Rheumatic Diseases* by Dr A G Signy, 5.15 p.m., *The Radiological Diagnosis of Arthritis* by Dr Grace Batten.

## Sunday

ST STEPHEN'S HOSPITAL RHEUMATISM UNIT, 369 Fulham Road, London, S.W.—Oct 24, 10 a.m. ward round, with demonstration of cases by Dr Philip Ellman, 11.15 a.m., (1) *Problems in Differential Diagnosis* and (2) *Drug Treatment in the Rheumatic Diseases* by Dr Ellman, 2 p.m., *Orthopaedic Aspects of Rheumatic Disease and the Prevention and Treatment of Deformities* by Mr A G Timbrell Fisher, 3.30 p.m., *Radiotherapy in the Treatment of the Rheumatic Diseases* by Professor B W Windeyer, 4.45 p.m., *Psychiatric Factors in the Chronic Rheumatic Diseases* by Dr David Shaw.

## Monday

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—Oct 25, 8.30 p.m. *Streptomycin*. Discussion to be introduced by Dr Jack Rubie and Dr Geoffrey Marshall. SOCIETY OF APOTHECARIES OF LONDON—In the Hall, Black Friars Lane, Queen Victoria Street E.C. Oct 25, 5 p.m. *Rheumatic Heart Disease and its Treatment* by Dr T F Cotton. UNIVERSITY COLLEGE, Gower Street, W.C.—Oct 25, 4.45 p.m. "The Electron Microscope and its Biological Applications" by Dr E M Crook, M.Sc., Ph.D.

## Tuesday

EUGENICS SOCIETY—At the Rooms of the Royal Society, Burlington House, Piccadilly, London, W, Oct 26, 5.30 p.m. *Legal and Social Implications of Artificial Insemination* by Mr Cecil Binney. All interested are invited to attend. INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Oct 26, 5 p.m. *Liver Function in Certain Diseases of the Skin* by Dr A D Porter. INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330 2 Gray's Inn Road, London, W.C.—Oct 26, 11.30 a.m. *The Physical Principles of Audiometry and Hearing Aids (I)* by Dr T S Littler, 4.30 p.m. *The Surgical Treatment of Deafness* by Mr Terence Cawthorne. INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C., Oct 26, 11 a.m., 'Pathology and Immunology of Syphilis' by Dr Cuthbert Dukes, at St Peter's Hospital, Henrietta Street, London, W.C., Oct 26, 5 p.m., 'New Growths of the Kidney and Ureter' by Mr Harland Rees. UNIVERSITY COLLEGE, Gower Street, London, W.C.—Oct 26, 1.15 p.m. *Visible Speech* by Dr D B Fry, Ph.D.

## Wednesday

GLASGOW UNIVERSITY DEPARTMENT OF OPHTHALMOLOGY—Oct 27, 8 p.m. *Histopathology of the Dracoma Angle* by Professor Loewenstein. INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C., Oct 27, 11 a.m., 'Diagnosis of Primary Syphilis' by Dr W N Mascall, at St Peter's Hospital, Henrietta Street, London, W.C., Oct 27, 5 p.m. *Disturbances of Micturition due to Nervous Disease and Injury* by Mr A W Badenoch. PLANNING FORUM—At Planning Centre Hall, 28 King Street, Covent Garden, London, W.C., Oct 27, 6.15 p.m. *Sexual Behaviour in the Human Male* discussion on the Kinsey Report to be opened by Dr David Mace, Ph.D., Dr Fred Grundy, and Dr E H Larkin. ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28 Portland Place, London, W.—Oct 27, 3.30 p.m. *Problem Families* by Dr C F Brockington. SOCIETY OF APOTHECARIES OF LONDON—In the Hall, Black Friars Lane, Queen Victoria Street E.C., Oct 27, 5 p.m. *Therapy as a Diagnostic Measure* by Professor H Cohen.

## Thursday

CHADWICK TRUST—At University College, University Park, Nottingham, Oct 28, 4 p.m. *Advances in Preventive Medicine during the War of 1939-45* by Sir Arthur MacNalty. DEWSBURY STAINCLIFFE GENERAL HOSPITAL—Oct 28, 5 p.m. *Some Recent Advances in Dermatology* by Dr F F Heller. EOBURGH ROYAL INFIRMARY—Oct 28, 5 p.m. 'Psychogenic Pain' Honyman Gillespie Lecture by Dr R G Gordon. INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C., Oct 28, 11 a.m. *The Primary Syphilitic Chancre and Differential Diagnosis* by Dr A H Harkness, 5 p.m. *Infertility in the Male* by Mr A R C Higham.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Keppel Street, WC—Oct 28, 5.15 p.m. *Micromethods in Biology* by Professor K. Linderstrom Lang (Copenhagen)

ROYAL LEGAL SOCIETY—At 26 Portland Place, W, Oct 28, 8.15 p.m. *Criminal Justice* by His Honour Judge W. G. Earengay, K.C.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury Square, London WC—Oct 28, 7.30 p.m. *The British Pharmacopoeia 1948* by Dr C. H. Hampshire

GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—Oct 28, 4.30 p.m. *Neurology and Psychiatry* Lecture demonstration by Dr Desmond Curran

SOCIETY OF APOTHECARIES OF LONDON—In the Hall, Black Friars Lane, Queen Victoria Street, E.C., Oct 28, 5 p.m. *The Management of Inoperable Malignant Disease* by Sir Stanford Cade

#### Friday

CENT AND CANTERBURY HOSPITAL, Canterbury—Oct 29, 5 p.m. Clinical meeting

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Keppel Street, WC—Oct 29, 5.15 p.m. *Enzymatic Break-down of Proteins (I)* by Professor K. Linderstrom-Lang (Copenhagen)

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, London, W—Oct 29, 8 p.m. *The V.D. Factor in Infertility and Sterility and its Treatment* by Mr Reynold H. Boyd

ROYAL INSTITUTE OF PHILOSOPHY—At University Hall, 14 Gordon Square, London, W.C.—Oct 29, 5.15 p.m. *Morality and Science* by Professor C. H. Waddington

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh—Oct 29, 8 p.m. *Cancer of the Large Bowel* by Mr R. Edmond

#### Saturday

BIOCHEMICAL SOCIETY—At London School of Hygiene and Tropical Medicine, Keppel Street, W.C., Oct 30, 11 a.m. *Partition Chromatography and its Application to Biochemical Problems* Symposium

## BIRTHS, MARRIAGES, AND DEATHS

### BIRTHS

Laidlaw—On Oct 10, 1948, to Mary wife of Dr W. Y. Laidlaw, Gramsdyke Avenue, Boness, a daughter

Morgan—On Oct 14, 1948, at Blighmont Nursing Home, Southampton, to Dr Dorothy Morgan, wife of Dr T. Keith Morgan, a son

### MARRIAGES

Latta-Hewison—On Sept 11, 1948, at St. Andrew's, Tilmanstone, near Sandwich, Kent, Flight Lieutenant Hugh Adrianus Llywelwyn Oswine Latta, M.B. B.S., to Margaret Scott Hewison, S.R.N.

Nabarro Cockrell—On Oct 2, 1948, at Rettendon, Essex, J. D. N. Nabarro, M.D. Lond., M.R.C.P., son of David Nabarro, M.D. F.R.C.P., to J. M. Cockrell, M.B. B.Ch.

### DEATHS

Boyd Roberts—On Oct 7, 1948, at Cunningham House, 103 Sutherland Avenue, London, W.9, Alexander Boyd Roberts, M.D.

Bryson—Recently, after a short illness, Michael Joseph Bryson, M.D., of 88 Malahide Road, Dublin

Croll—On May 4, 1948, Colonel David Gifford Croll, C.B.E., A.A.M.C.

Dingle—On Oct 2, 1948, Frederick Robert Dingle, M.R.C.S., L.R.C.P., of 3 Walker Terrace, Gateshead-on-Tyne, Co. Durham

Hemsted—On Oct 7, 1948, at Notrees, Kintbury, near Newbury, Berkshire, Edmund Spencer Hemsted, M.R.C.S., L.R.C.P., aged 79

Lacey—On Oct 3, 1948, Charles Edward Lacey, M.B., Ch.B., D.P.M., of 7 Windmere, Lytton Grove, Putney, London, S.W.15, at the National Hospital, Queen Square, London, W.C., after a brief illness, aged 29

Lewis—On Sept. 24, 1948, at Oswestry and District Cottage Hospital, William Henry Lewis, M.B., C.M.E., J.P., High Sheriff of Montgomeryshire, 1935-6, aged 82

McCarthy—On Oct 3, 1948, John McDonald McCarthy, Colonel, late R.A.M.C., retired, at The Torbay Hotel, Sidmouth

Malcolm—On Oct 6, 1948, at Kenwood, 322 Gilmerton Road, Liberton, Edinburgh, John Wright Malcolm, O.B.E., M.C., M.B., Ch.B., Ed., Lieutenant-Colonel, R.A.M.C.

Morrison—On Oct 7, 1948, Frederick Alexander Morrison, M.B., Ch.B., of Peel Isle of Man, late Boston Street, Hulme, Manchester

Moyers—On Oct 2, 1948, at Standen Brundall, near Norwich, William Francis Alexander Patrick Moyers, M.D.

Porter—On Oct 4, 1948, suddenly, at 124a Redland Road, Bristol 6, Charles Porter, M.A. Oxon., M.R.C.S. Eng., L.R.C.P. Lond., aged 56

Potts—On Sept. 25, 1948, at Lauriston, Wyke Hill, Woking, Surrey, Edmund Thurlow Potts, C.M.G., D.S.O., M.D., Ed., Lieutenant-Colonel, R.A.M.C., retired

Protheroe Smith—On Sept. 20, 1948, at Crediton, Devon, Eva, the wife of Edward Protheroe Smith, M.R.C.S., L.R.C.P. (late of Redditch)

Sass—On Sept. 30, 1948, at Deal, Frederick J. Wilfred Sass, M.R.C.S., L.R.C.P., D.P.H.

Shubik—On Sept. 20, 1948, at Oxford, Dr Nancy Shubik (née Rogers), M.R.C.S., L.R.C.P., wife of Dr Philippe Shubik

Square—On Sept. 23, 1948, James Elliot Square, F.R.C.S., of Plymouth, aged 89

Stewart—On Sept. 16, 1948, at Sleights, William Stewart, M.B., Ch.B., Ed., late of Southampton

Symonds—On Sept. 24, 1948, Jeffrey Isert Symonds, M.B., Ch.B., of 1, Redditch, aged 33

Western—On Oct. 19, 1948, suddenly, at his house, The Corderies, Chalford, H. T. S. Wood, Gloucestershire, George Trench Western, M.D.

## Any Questions?

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

### Recurrent Parotitis

**Q**—What is the aetiology and have there been any recent advances in the treatment of recurrent non-infective parotitis?

**A**—Recurrent parotitis is an uncommon disorder which, although non-infectious, cannot be called non-infective. It appears to be due to repeated exacerbations of an ascending infection of Stensen's duct. In some the predisposing cause is a calculus or a fibrous stricture of the duct, but in many oral sepsis has been held responsible. Sialography will often show a dilatation of the smaller ducts with a skiagram reminiscent of bronchiectasis. The fundamentals of treatment are to exclude stone and stricture or, if present, to treat by removal of the former and dilatation of the latter, to treat infective foci in the mouth, and to encourage drainage from the gland. This last may be done by massaging and expressing secretion, and by increasing the flow of saliva by means of acid drinks, such as lemonade, and the regular use of chewing-gum.

### Galactorrhoea

**Q**—What treatment should be given to a patient aged 32 whose breasts have been loaded with milk since the birth of her only child over two years ago? She has been having stilboestrol and hexoestrol 1 mg t.d.s. together with magnesium sulphate and a restricted fluid intake with little effect. The secretion is of a thick cheesy consistency at times at other times it flows rather freely.

**A**—Two counter-questions arise in this case: (1) How long was breast-feeding maintained? (2) Is the galactorrhoea accompanied by amenorrhoea? A rare but well-known syndrome associated with the names of Chiari and Frommel is characterized by prolonged lactation and amenorrhoea with superinvolution of the uterus. Its cause is unknown, but it is reasonable to suppose it to be the result of a disturbance of the pituitary whereby its lactogenic activity is maintained at the expense of its gonadotrophic function. Other causes of galactorrhoea are diseases of the hypothalamus and pituitary (acromegaly, for example), and it has also been described in association with lutein cysts of the ovary and even failure of ovarian function. The above possibilities should be excluded, but a more simple explanation should be kept in mind. Lactation can be maintained for long periods, if not indefinitely, by local stimulation of the breasts, and, if this patient is continually attempting to express the discharge to confirm its presence that might be enough to account for its persistence. Moreover, the dose of stilboestrol which has been given is scarcely enough to suppress lactation, it might even have a stimulating effect.

If a cause cannot be found it may be difficult to treat the condition successfully. The breasts should be well supported and all forms of manipulation avoided. The dose of stilboestrol should be increased up to 10 or 15 mg daily (in divided doses), and continued for seven to ten days then gradually decreased during the following week. If that fails, testosterone propionate in large doses might be tried. A suitable dose would be 25 mg intramuscularly three times weekly for two weeks. It should not be continued for longer than this lest it produce virilism.

### Gentian Violet for Skin Infections

**Q**—Is gentian violet 1 or 2% solution still a recognized treatment for Gram-positive skin infections or ulcers?

**A**—Gentian violet remains a most valuable application for skin infections. If there is much exudate or discharge gentian violet may give trouble by obstructing its flow if used as the lotion, but by using it in ointment form with an emulsifying base this difficulty can be avoided.

## Adrenaline, Procaine, and Pulmonary Oedema

**Q**—Can acute pulmonary oedema occur as the result of a local injection of procaine? I saw a man aged 45 who had tender nodules in the fascia of the back of the neck at the level of the fourth cervical vertebra. I injected 2 ml of 2% procaine with adrenaline taking care not to enter a vein. Two minutes later the patient turned pale and felt faint, pulse 130. After another minute he experienced a tight sensation in the chest and coughed up about 2 oz (57 ml) of frothy heavily blood-stained sputum. Morphine gr  $\frac{1}{4}$  (16 mg) with atropine gr 1/150 (0.375 mg) was administered. Though the chest was full of rales during the attack, four hours afterwards there were only some fine crepitations at the left base. The heart was normal and the blood pressure remained at 80/30 mm throughout. It seems highly probable that the procaine caused the pulmonary oedema. Intravenous injection can almost certainly be excluded since the site was relatively avascular, the usual precautions were taken and no signs of accidental intravenous injection were noted.

**A**—It is always dangerous to say that something can never happen and therefore it is dangerous to say that procaine can never cause acute pulmonary oedema. Such an occurrence has not been recorded before. On the other hand, adrenaline can cause acute pulmonary oedema, so that it seems more likely that the adrenaline injected was responsible for the symptoms. The patient must have been unusually sensitive to the drug for this to happen. The theory of the production of acute pulmonary oedema by adrenaline is that this drug releases histamine in the body, as it has been shown to do, and the histamine then causes the oedema. In support of this theory is the fact that the acute pulmonary oedema can be arrested by the injection of antihistamine compounds.

## Paper-eating Infant

**Q**—Can you advise me how to treat a child of 2 years who is continually eating paper? He weighed 6 lb 2 oz (2.8 kg) at birth and did well up to the age of 8 months, when he stopped gaining. He then started to eat paper and would eat very little of his ordinary food. He eats any paper that is left about and it passes through him undigested. He is pale and has a protruding abdomen but otherwise appears normal. He walked at the age of 13 months and is now talking well.

**A**—Between the ages of 2 and 3 years food fads are at their peak. These are not uncommonly associated with anxiety arising out of habit training in the course of which the small child goes through a phase of over-emphasized disgust at his own excreta. Since food can also be messy, he may experience a revulsion against this. The eating of paper, which symbolizes cleanliness through its toilet use, is likely in the logic of infancy to represent 'inner cleanliness'. In this case practical measures would include making 'potting' as easy and informal as possible, the avoidance in diet of food that may arouse disgust (such as sausages or anything brown and of 'messy' consistency) and the provision of play material with which the child may experiment and work out his fantasies. Sand and water plasticine, and clay are all useful in the latter respect. It may be advisable to keep paper out of reach so far as possible though not openly to deny it when asked for. If these measures do not prove effective, the child should be taken to see a psychiatrist.

## Lactating Baby

**Q**—Can you suggest treatment to stop a flow of milk from the right breast of a male baby aged 10 days? The right breast is slightly larger than the left which is normal and dry.

**A**—Transient enlargement of the breasts in newborn babies is not unusual and is supposed to be due to the high concentration of maternal oestrogens. Another theoretical factor is hyperplasia of the baby's adrenal cortex, with resulting secretion of oestrogens. An actual secretion of milk is rare in itself and especially one that persists. It is probable that an injection of 10 mg of testosterone, repeated daily if necessary, would stop the secretion. Apparently the left breast is unresponsive to the supposed hormone stimuli, and this lack of response is met with in other types of endocrinological reaction.

## Income Tax

## Refund of Superannuation Deductions

J has in the past suffered deductions from his salary under a superannuation scheme. His post has been abolished and the amounts deducted refunded with interest. Is the refund to be reckoned as 'income'?

\* \* The element in the total payment which represents interest will rank as income, but probably taxed at source. The remainder of the total refund represents postponed payment of small amounts of salary for past years which hitherto have not borne tax. It may be, however, that the tax to be accounted for on that basis has been allowed for in calculating the net amount of the refund. We suggest that inquiry be made of the town clerk as to the details of the calculations of the net refund, when the position as regards tax will probably be clear.

## NOTES AND COMMENTS

**Profuse Sweating in Acute Rheumatism**—Dr A. D. McDwyer (Dublin) writes: This sign ('Any Questions?' April 3, p. 672) sets a problem in diagnosis I have already discussed (*B.M.J.* 1947, 1, 310). Increased perspiration, especially profuse at night, may precede all local manifestations of rheumatic fever, it is constant even apart from salicylates, and the last of all clinical signs and symptoms of active infection to disappear. In the chronic infective disease all degrees of sweating, perhaps varying with the toxæmia, are seen, from a persistent profuseness throughout the twenty-four hours, or between noon and 4 a.m., or 9 p.m. and 2 a.m., to an individual "night sweat." Experience generally verifies the observation,<sup>1</sup> thus fatigue, a chill, an adventitious infection, a slight injury, a touch of indigestion, a mental upset or increased bodily activity may cause the rheumatic to relapse from the quiescent into an acute febrile state." More sensitive still is the chronic active rheumatic, hence the sweating—so long as it continues and unless cared for correctly—and the resultant damp clothes may cause a vicious circle of reactivation or exacerbation. The usual hospital practice and nursing routine are inadequate for such cases, as the need for well-aired clothes is paramount over and above the degree needed for non-rheumatic patients, freshly laundered clothes and bed linen returning from a laundry need a minimum of twenty-four hours at not less than 130° F (54° C), personal garments need the same temperature for varying periods but not less than six hours (such clothes should not be stored in unheated presses).

Resulting from this special care, these patients sleep better, are free from the myalgia and other aches—now their common lot—sweat less, and the tachycardia lessens. Further precautions are freedom from draughts, room temperature not above 64° F (17.7° C) (hot weather invariably causes an exacerbation), avoidance of general bed baths, local ones restricted and given with care, those in attendance free from nasopharyngitis, bed rest, of course, and the frequent change of damp clothes even during sleep, for then they may dry on the patient and cause a chill. (Most of this applies generally to cases of idiopathic rheumatoid arthritis with active infection.) On such a regime chronic active rheumatics show remarkable improvement, for it helps to keep the toxæmia at a minimum and in the acute primary attack lessens the danger of chronicity.

## REFERENCE

**Delay in Receiving B.M.J.**—In recent weeks special arrangements have been made with the Post Office to try to ensure that copies of the *British Medical Journal* reach most of our readers in Great Britain on the Saturday morning. It would help us to assess the effect of this scheme if those who still receive the *Journal* late would be good enough to forward to the Publishing Manager at B.M.A. House wrappers of copies which are delayed, with a note of the time of their arrival.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: Alltophys, Westcott, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: Britmedads, Westcott, London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: Medisecra, Westcott, London.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 23 1948

## LETTER TO ALL MEDICAL PRACTITIONERS

*The following letter has been sent by the Secretary of the British Medical Association to every medical practitioner in England and Wales and Scotland*

The purpose of this letter is to explain the present position in relation to the remuneration of doctors under the new Service. In some ways the picture is yet incomplete. But it will, I think, be useful to describe the position as it stands to-day. More space is devoted to general practitioner remuneration simply because more is known about it at the moment.

### General Practitioners

Before the war the total professional incomes of general practitioners in England, Wales, and Scotland added together amounted to rather more than £28 million. The total remuneration provided under the N.H.S. Acts for general practitioners is approximately £45 million.

It would not be enough to remunerate general practitioners only for those persons who are on their lists, for there is always a risk that they may be called upon to treat people not on anyone's list—in fact, they are at risk for other persons without knowing it. A guess has therefore been made as to the proportion of the community which will use the general practitioner part of the service. For the first two years, and subject to review at the end of that period, the guess has been made as 95% of the community. Figures which have been published for the proportion of the population which has signed on doctors' lists should be treated with the utmost reserve. In fact, the figures are inflated because E.C.I.'s have been filled up in respect of a large number of persons insured under the old N.H.I. scheme despite the fact that such persons were transferred *en bloc* to the new Service. In one area the number of persons alleged to have signed on is 111% of the total population of the area! Local executive councils are working to eliminate this inflation, and until the job is complete it will not be known what proportion of the population has in fact joined the doctors' lists. It is likely to be below 95%. Anyway, general practitioners in the Service will be paid for 95% of the population during the first two years of the Service.

Taking the population at 47½ million, 95% amounts to 45 million. Multiply 45 million by 18s and the result, some £40 million, is the sum of money which belongs to general practitioners and which will be distributed in full to general practitioners in each year. 7d of the 18s—some £13 million in all—is set aside as the Mileage Fund. The 17s 5d is the amount paid into the central pool for each one of the 45 million persons.

Bearing in mind that the quarterly payments are provisional payments on account, what will the annual capitation be? If 95% of the population sign on all inflation dealt with, and ignoring the basic salary, the annual payment per person on the list will amount to 17s 5d. To the extent to which less than 95% of the population sign on, the average payment per person on the list will be more than 17s 5d. This is an annual payment based on annual calculation.

### Distribution of the Central Pool

Now for the distribution of the central pool. First it is divided into two pools, one for England and Wales and one for Scotland. The distribution of each national pool is controlled by a committee on which general practitioners are represented. Distribution is made on lines almost identical with those under N.H.I. In pre-war days under N.H.I. there went into the pool for medical treatment 9s in respect of every insured person. Under the N.H.S. there goes into the pool 17s 5d in respect of 95% of the population. 5% is kept back from the quarterly

provisional payments in a central reserve pending the final distribution for the year, when it is paid out. Nothing can be left in the kitty at the end of the year. The 5% reserve is necessary because of the inflation of doctors' lists and to provide for temporary residents.

Now for the first quarter's payment. 5% is retained at the centre and approximately one-fourth of the remainder was distributed among local executive councils for the provisional on-account payment on Oct 1. (It was not quite one-fourth in the first quarter because N.H.I. covered the first four days of the quarter and payment at the old rate is made for those four days.)

This share-out between local executive councils could have been on the basis of population but that would not have been fair because in one area the proportion of people using the Service is higher than in another. It could have been on the basis of the number of persons who signed on doctors' lists in the various areas, but that would not have been fair because the doctors in an area with, say, 80% people signing on are under a risk that 20% may subsequently sign on, while the doctors in an area where 99% of the population sign on are only under a risk that 1% may subsequently sign on. Therefore it was provisionally decided that the pay-out to local executive councils should be on the basis of the number who have signed on doctors' lists plus one-third of those in the area who have not. This method of distribution may have to be reviewed. The point to remember is that the final share-out is complete and the formula is used merely to divide as equitably as possible a certain sum of money between a number of local executive councils.

### Distribution of the Local Pool

We now reach the stage that the local executive council has got its provisional share of the central fund. This money has to be paid out to doctors in the proportion of the number of persons who have signed on their lists. In the old days of N.H.I. this is in fact what happened. But under the new order there are certain other factors. Practitioners who prove to the satisfaction of the local executive council after consultation with the local medical committee that they need basic salaries—and only those who make application and so prove are entitled to them—will be paid £300 a year with a reduction of one-seventh in their capitation payments. In the case of practitioners with lists under 2,350 the basic salary means to them a higher payment per patient. These basic salaries come from the local pool, and therefore any additional payment per patient the recipients receive comes from the remuneration of their colleagues. But the point is that many local executive councils have kept back a certain amount of money pending the consideration of applications for basic salary. The amount retained may well prove to be an over-estimate. Secondly, the superannuation scheme requires the deduction of 6% from the net remuneration, 35% being regarded as practice expenses. (In the case of mileage payments, one-half is regarded as expenses.) Practice has varied, but a number of local executive councils have kept back the 6% for the doctor's contribution.

There is a further factor which tends to bring down the quarterly rate though not the annual payment. Lists are still inflated with some insured persons appearing twice on the list. This means that at least in the first quarter payment is being made in respect of a larger number of persons than really exist on doctors' lists. All this will be caught up in the final pay-out.

The deductions made, the rest is paid out in proportion to the number on doctors' lists, the calculation being made on a count taken some time in August. To take London as an example, the local pool received 4s 6d for every person estimated to be on doctors' lists, the deductions amounted to 9d,

and 3s 9d was paid out to London general practitioners. In subsequent quarters it will be possible to estimate more accurately the amount if any, needed for basic salaries. In addition, the work of cleaning the lists to remove inflation will go on. Even so it is the annual payment, which will take the form of a final adjustment for the year, which brings the remuneration up to at least 17s 5d per person on doctors lists (and more to the extent to which less than 95% of the population sign on).

There is other money. The Mileage Fund, which consisted in pre-war days of £250,000 and before the appointed day of about £600,000 now stands at £1,300,000. Mileage payments are made twice a year. The first payment is a purely provisional and conservative one of  $1\frac{1}{2}$  times the old half-yearly mileage cheque under the N.H.I. system. A new model mileage scheme now under consideration will be submitted for the consideration of mileage areas, and the final payment for the year, with the full disbursement of the £1,300,000, will be made on the basis of the new mileage scheme.

Over and above the ordinary pool there is an additional fund called the Inducement Fund, amounting to some £400,000 a year, which is to be used to attract doctors to areas which would not otherwise provide a sufficient living or to keep doctors in such areas. Clearly, the bulk of this money will go to rural and semi-rural areas. The procedure is for individual practitioners to apply to the local executive councils and for those councils, after consultation with local medical committees to recommend an award to the Medical Practices Committee. Practitioners desiring to claim from this fund should make application to their local executive councils. No payments have yet been made. Maternity fees are additional, as are payments for immunization and vaccination, the rates for which have yet to be negotiated. There will be in certain cases special grants for training assistants, payments for drugs, and sessional fees from local health authorities.

*So far I have referred only to the method of distribution and not to the over all sufficiency of the remuneration. The Insurance Acts Committee (General Medical Services Committee) has begun to prepare the case for a revision of the remuneration arrangements generally. It will examine the current position in the light of the information available at the end of the first quarter and give special attention to the question of the permitted maximum on doctors lists and to the position of those who by the nature of their areas of practice cannot achieve the bigger lists. We are aware of the difficulties and will do our best to resolve them.*

#### Consultants and Specialists

In this field the next stage is the negotiation of a national framework of remuneration based on the Specialist Spens Report. The Ministry has promised shortly to produce, as a basis of negotiation, its translation of the recommendations of the Spens Committee into draft scales of remuneration. It is anticipated that such scales, once agreed with the profession, will come into operation on or before March 31, 1949 but will be retrospective to July 5, 1948. The provisional interim scales, which were not the subject of prior negotiation with the profession, are no more than a basis for "on account" payments, and the profession is in no way committed either to the method, the amounts or the limitations embodied in those scales. In the meantime the Central Consultants and Specialists Committee in consultation with its regional committees, is scrutinizing the Specialist Spens Report and formulating its views on the more important features of the Report.

#### Public Health Service

Negotiations are about to begin on the revision of the public health service remuneration in the light of the two Spens Reports. The one set of negotiations will cover both the medical officers of local health authorities and the medical officers of other local authorities. Already we have notified the Ministry and through them, the associations of local authorities of our proposals.

#### Other Branches

Practitioners in other fields of medicine will naturally be wanting to know what is being done to secure an upward revision of their remuneration. In general, the answer is that

the Association will seek the application in the most appropriate way of the standards of the Spens Reports to other groups of the profession, including the armed Forces, the Colonial Medical Service, the university professors and teachers, and others. For the first time we have ranges of remuneration accepted by the Government as appropriate to large sections of the profession and we shall seek their proper application to groups not specifically covered by the two Spens Reports.

#### Superannuation

It may be convenient to add a few brief points on the subject of superannuation of general practitioners and consultants.

The Government contribution is 8%, the employee's contribution is 6% applied to the net remuneration.

The net remuneration is the full remuneration in the case of consultants and 65% in the case of general practitioners, the remaining 35% being regarded as practice expenses (50% for mileage). A practitioner in partnership practice will pay contributions—and so receive superannuation—on the basis of his share of the partnership (instead of on the payments received by him from the executive council) provided particulars of the partnership deed are disclosed to the executive council.

For those who serve for 10 years or more the benefits on retirement are a pension and a cash payment.

To calculate the pension of general practitioners and part-time specialists, add up the net remuneration for the years of superannuable service, calculate  $1\frac{1}{2}\%$  of this aggregate sum, and the result is the annual pension payable at or after age 60.

The single cash payment amounts to  $4\frac{1}{2}\%$  of this aggregate sum in the case of single men and  $12\%$  in the case of married men, whose wives will be eligible for widow's pension.

For whole-time consultants and specialists and others in salaried employment the pension is based on the average annual remuneration during the last 3 years' service.

To calculate the pension take  $1/80$ th of this amount and multiply it by the number of years of contributing service. The same calculation will give the cash payment in the case of married men, whose wives will be eligible for widow's pension. In the case of single men the cash payment will be three times as much.

Those who do not serve for 10 years normally receive no pension but after 5 years' service will be eligible for the cash payment on retirement at age 60 or more, or for a short service gratuity if permanent incapacity supervenes, or for a death gratuity, or, if none of these benefits is payable, will receive back their contributions with  $2\frac{1}{2}\%$  compound interest.

There is one further point—immediately on entering the Service a practitioner is eligible for an injury pension in the event of permanent incapacity through accident or injury sustained while on duty and attributable to the nature of his work.

#### General

This is a bird's-eye view of the remuneration position as it stands to-day. As developments occur, the profession will be kept in touch with the changing position through the columns of the *British Medical Journal*. A great deal of work has been done and is being done on behalf of the profession by those whose heavy responsibility it is to represent them. I recognize the need to keep the profession more fully informed of what is going on, and this letter is intended to be a step in that direction.

CHARLES HILL  
Secretary

#### CLAIMS FOR COMPENSATION

Practitioners are reminded that except where delay is unavoidable the form of application for compensation must be completed by the applicant and delivered or sent by post to the Minister on or before Oct 31, 1948.

#### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar  
*Non County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton le Spring, Huyton-with Roby, Redditch (restricted to new appointments) Tyldesley

## Correspondence

### Relation with Executive Councils

SIR—In the *Supplement* of Oct 9 (p 134) there appeared letters by Drs Hugh M Tucker and D Gwyn Jones respectively which seem to suggest that the Crown or the local executive council can be regarded as the employers of practitioners engaged in the provision of general medical services for the insured population. The statement issued by the Ministry of National Insurance to the effect that doctors in private practice or on the lists of executive councils were self-employed persons is challenged, and, what is equally important, the observation is made by one writer that practitioners in public practice are employed by the Crown and are responsible to the Crown or the Ministers thereof for any mistakes they may make in the carrying out of their duties. This assertion is not strictly correct when one has regard to the legal relationship subsisting between a practitioner on the list of an executive council and the executive council concerned. Such practitioners should be regarded, as their counterparts were regarded under the National Health Insurance Acts, as contractors, they are not employed under a 'contract of service' but presumably under a 'contract for services' to those persons who choose to avail themselves of these services by following the administrative procedure laid down under the regulations.

There is a danger that some readers might assume from the observations of your correspondents that their medico-legal liabilities will be shouldered by the State, and that the interests of the State and of the practitioners in such matters will run on parallel lines. Nothing could be further from the truth, since it can be asserted without fear of contradiction that claimants can still and will look to practitioners for compensation for injuries sustained as a result of some act or omission arising in the course of the conduct of their professional duties. It is possible that on occasion the Crown may also be involved, but that will not of itself release the practitioners from their personal legal liabilities.

Furthermore, the Crown and its legal advisers may on occasion adopt a line of action in handling a claim by a patient or his relatives based on alleged negligence which will operate to the professional disadvantage of the practitioner concerned. It is therefore necessary more than ever that practitioners should continue to protect themselves against legal claims by remaining members, or applying for membership, of a reputable defence organization from which they can obtain independent medico-legal advice and protection. It is contemplated that in future practitioners will find it increasingly necessary to look to their defence organizations for legal advice, protection, and intervention on matters affecting their professional wellbeing—I am, etc

ROBERT FORBES,  
Secretary

### Simple Issues

SIR—Before we acquire a new set of conditioned reflexes and learn to kowtow three times as each new regulation drops on our breakfast tables cannot we decide just where we stand over one or two simple issues? The campaign against private practice rests on the belief that all men are equal. Who are we to say that the appendicitis of a beer-sodden tramp is as important as that of an FRS? A decent society pays more money to its most valuable citizens precisely that when they are ill they can pay for privacy, medical priority extra care, and comfort. If this is true, we should fight for the rights of the private patient, if untrue, let the busy politician, scientist, poet, or managing director wait his turn with the charlady. But do let us make our minds up about it.

Again is a doctor's duty to his patients or to the administrative machine? Are we to see that Bill Jones gets well or that he gets his cash pay? If we are to have our time free for doing the administration simply must cut its demands for form filling to what we not Whitehall regard as a minimum. If the National Insurance Act is more important than the National Health Service Act let us be told so, so that we know where we are.

Lastly, health centres are an idea of co-operation as well as a blue-print of a building. Buildings may have to be deferred but co-operation could begin now. It would begin if each afternoon I could ring up the office for my district and say, "Please get Bill Smith into hospital for appendicitis, arrange a barium meal for Mrs Thomas, send someone to collect a specimen for the lab from my surgery, find out how Elsie Spinks is in the mental hospital, and get the district nurse to visit old Tom Jones," and know that all those things would be done without more bother on my part. It could be improved if school clinics and antenatal clinics sent me regular reports on such of my patients as they see. There are many ways in which a really keen administration could actively help doctors now in the health centre spirit without waiting for the bricks and mortar—I am, etc,

Ashted Surrey

W EDWARDS

### Implementation of Spens Report

SIR—There is little doubt that all general practitioners, with the possible exception of those in congested industrial areas will suffer a diminished gross and net income as a result of the inadequate capitation fee. In addition to this it is common knowledge that work has increased. The increase arises from two sources: first, the increase in the number of items of service given to women and children, secondly the increased attendance by former insured persons for ophthalmic and other services. This second group is likely to diminish, but the first will increase still further as time goes on.

One hears with distress of cases where doctors are having seriously to consider taking their children away from public schools of having to cut out "extras," of not being able to send their second and third sons to the same school as their first on account of reduced incomes. This is not due to decreased popularity of the doctors, for they are working harder than ever. These doctors are the salt of the earth as far as general practice is concerned. At the same time it is generally known that it has been laid down by the Minister that staffs of insurance committees and hospitals absorbed into the new service should be no worse off in the new than the old regime.

That the Minister confidently anticipates that the work will increase is obvious from his statement that he expects the prescription rate to be in the region of 150,000,000 per annum. This in my view is a low estimate.

That the general practitioner, who after all is the mainstay of the Service without whose co-operation it cannot exist, is to be the worst hit financially is entirely unjust. The same principle should apply—namely that he shall at least be no worse off under the new Service than the old. This principle was the basis of the Spens Report. It should be implemented forthwith and not at a later date. This is an issue on which we can unite much more readily than on the seven principles. Let this year's conference of local medical committees make it quite clear that we went into this Service on the understanding that the Spens Report would be fully implemented and that we can come out of it if it is not—I am, etc,

Solihull Warwickshire

ARTHUR BEAUCHAMP

### Obstetric Committees

SIR—It has been for some years an accepted principle that the district midwife should be able when necessary to secure the services of a general practitioner with special knowledge of midwifery. The Midwives Act of 1936 made special provision for the setting up of panels of practitioners skilled in obstetrics, but for reasons no longer of interest no action was taken by the local health officers, and this section of the Act remained inoperative. Within recent years the necessity for a special panel of doctors to support the district midwife has been stressed by the Royal College of Obstetricians in their admirable pamphlet *A National Maternity Service*. It was therefore a relief to find that such a panel of obstetric practitioners was specially mentioned and provided for in recent legislation.

Obstetric committees, set up for the purpose of selecting practitioners skilled and experienced in midwifery, are evidently finding the task a most difficult one, but I submit, Sir, that the solution is not to be found by the admission *en bloc* of all practitioners in a given area. This procedure will defeat the entire purpose of this section of the Health Act and render it

I am persuaded, Sir, that steps can and must be taken to obviate this debacle which threatens the efficiency of the maternity services of the country at the very moment of their inception—I am, etc.,  
WILLIAM J CLANCY,  
Sheffield Obstetric Officer and Deputy Medical Superintendent

### Prescribing in NHS

SIR—Dr M Lichtenstein (*Supplement* Sept 11, p 121) complains of yet another pad of forms (EC10A) to clutter up his desk. To be issued soon, it will enable practitioners in Scotland to prescribe for themselves, without restriction, any drugs or appliances which they may need to stock or restock their surgeries and bags. Although Dr Lichtenstein's point is clear it is a little ironical that he should pick on this particular form for his complaint, since it is one with which we weaker brethren south of the Border are not to be entrusted at all. Instead we are offered 2s 6d per 100 patients per annum, a sum which I calculate will barely cover the cost of roller bandages used in the surgery.

One presumes that this niggardly arrangement is intended to prevent the subsidizing of private practice by the State. But, Sir, has private practice been entirely eliminated in Scotland? If not, why this difference in the regulations? The insinuation against the practitioners of England and Wales is unpleasant—I am, etc.

Billinghurst Sussex

L C BOUSFIELD

### POINTS FROM LETTERS

#### Finding Employment

Dr MARTIN LUDLAM (Edinburgh) writes: We were told by our elders and betters that the Health Service was all but unworkable because of the lack of medical men. So far, however, the Service seems to manage fairly well and be economical in its requirements. The winter may tell a different story. Some of us can be excused for feeling that the B.M.A. and others were too much concerned with 'principles,' which often savoured of mere prejudice or propaganda and not enough with good honest self-interest. Time and time again we were warned of the power of the Minister, and on paper he has much, but in practice we may well find that it is the quality, efficiency, and attitude of the local committees that will mould the future of general medical practice. Power will be with them, particularly the medical committees. It is from them that the young medical is likely to meet opposition. The young medical writing to all the executive councils from Haddington to Humber, from Perth to Lancashire, is likely to receive neither hope nor counsel nor encouragement. A sympathetic reply is occasionally received from a clerk with some human feeling. Sometimes you get no reply at all. And for those with wife and family like myself there are other serious considerations. There comes a time when, apart from other considerations, family separation necessitated by a life of assistantships and locums becomes intolerable. Hope, faith, some capital, and permission to squirt at the moment offer something. But I fear both hope and faith and capital will have much decreased before permission or otherwise comes through. We have so far only touched the problem and that in only very general terms. I would, however, suggest to the would-be squatter that, having found out the size of the population and the number of doctors practising in that area, he should be bold and resolute, and that he should use his common sense, that if good accommodation comes on the market he should not delay in obtaining it, that if local executive councils consider his application adversely he should not be unduly influenced, that medical practice committees and lay members of other committees are likely to be on his side, that local medical committees will be against him. He should also realize that when a doctor dies or retires his practice is not automatically advertised and that his panel list is likely to be quickly swallowed by others already in the locality.

#### Standard Size for Filing

Dr W S SYKES (Morley, Yorks) writes: Let us have a standardized pocket sized loose leaf system. A pocket binding case could contain a loose-leaf formulary (for easy correction and revision) and will also hold lists of hospital staffs and time-tables of out patients, addresses and telephone numbers of local hospitals, etc. Another file on the desk could contain the rest, not likely to be needed when visiting. Rigid standardization of size is necessary so that leaves from many different sources and areas may all fit.

#### Raise Capitation Fee

Dr WILLIAM H SCOTT EASTON (Frinton-on-Sea) writes: Instead of appealing to patients to forgo their rights the B.M.A. should remove the cause of the threatened winter avalanche by negotiating the raising of the capitation fee to a level which would enable the doctors to make a living without taking excessive numbers on to their State lists.

## Association Notices

### SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award.

1 The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research and record in general practice, it includes a money award of the value of 50 guineas.

2 Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3 The work submitted must include personal observations and experiences collected by the candidate in general practice and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4 Essays, or whatever form the candidate desires his work to take must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec 31, 1948. The prize will be awarded at the Annual General Meeting of the Association to be held in 1949.

5 No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6 If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7 Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

8 The writer of the essay to whom the prize is awarded may on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9 Inquiries relative to the prize should be addressed to the Secretary.

### RECONSTITUTION OF ASSAM AND NORTHERN BENGAL BRANCH

The Assam and Northern Bengal Branch, together with the Assam Valley, Northern Bengal and Dooars, and Surma Valley and Chittagong Divisions, have now been reconstituted into two Branches with the following designations: Assam Branch, Northern Bengal and Dooars Branch.

The change comes into effect as from the date of publication of this notice.

CHARLES HILL,  
Secretary

### Diary of Central Meetings

OCTOBER

27 Wed Council, 10 a.m.

### Branch and Division Meetings to be Held

EDINBURGH AND SOUTH EAST OF SCOTLAND BRANCH—Tuesday Oct 26 8.30 p.m. B.M.A. Lecture by Dr E. Arnold Carmichael 'Recurrent Lapses in Consciousness. Some Points in Diagnosis and Treatment.'

MID HERTS DIVISION—At Cell Barnes Recreation Hall Friday Oct 22, 8.45 p.m. Annual general meeting. Election of officers for 1948-9 etc.

MONMOUTHSHIRE DIVISION—At Royal Gwent Hospital Newport Mon, Thursday Oct 28.

SOUTH ESSEX DIVISION—At Tilbury Hospital Friday Oct 24 9 p.m. Mr A. M. A. Moore 'Surgical Anatomy in General Practice.'

TUNBRIDGE WELLS DIVISION—Week-end refresher course Saturday Oct 23, and Sunday, Oct 24. Dinner at Beau Nash Club 7 p.m. Pantiles, Tunbridge Wells, at 7.45 for 8 p.m. Sir Herbert Easton, president of the General Medical Council, will speak at the club at 9 p.m. and not at the Kent and Sussex Hospital at 8.30 p.m. as previously announced.

LONDON SATURDAY OCTOBER 30 1948

## STREPTOMYCIN TREATMENT OF PULMONARY TUBERCULOSIS A MEDICAL RESEARCH COUNCIL INVESTIGATION

The following gives the short-term results of a controlled investigation into the effects of streptomycin on one type of pulmonary tuberculosis. The inquiry was planned and directed by the Streptomycin in Tuberculosis Trials Committee, composed of the following members: Dr Geoffrey Marshall (chairman), Professor J W S Blacklock, Professor C Cameron, Professor N B Capon, Dr R Cruickshank, Professor J H Gaddum, Dr F R G Heaf, Professor A Bradford Hill, Dr L E Houghton, Dr J Clifford Hovle, Professor H Raistrick, Dr J G Seadding, Professor W H Tytler, Professor G S Wilson, and Dr P D Arey Hart (secretary). The centres at which the work was carried out and the specialists in charge of patients and pathological work were as follows:

*Brompton Hospital London*—Clinician Dr J W Crofton, Streptomycin Registrar (working under the direction of the honorary staff of Brompton Hospital) Pathologists Dr J W Clegg Dr D A Mitchison  
*Colindale Hospital (LCC) London*—Clinicians Dr J V Hurford Dr B J Douglas Smith Dr W E Snell Pathologists (Central Public Health Laboratory) Dr G B Forbes, Dr H D Holt  
*Harefield Hospital (MCC) Harefield Middlesex*—Clinicians Dr R H Brent, Dr L E Houghton, Pathologist Dr E Nassau

*Bangour Hospital Bangour West Lothian*—Clinician Dr I D Ross, Pathologist Dr Isabella Purdie  
*Killingbeck Hospital and Sanatorium Leeds*—Clinicians Dr W Santon Gilmore, Dr A M Rennie Pathologist Professor J W McLeod  
*Northern Hospital (LCC), Winchmore Hill London*—Clinicians Dr F A Nash Dr R Shoulman, Pathologists Dr J M Alston Dr A Mohun  
*Sully Hospital Sully Glam*—Clinicians Dr D M E Thomas Dr L R West Pathologist Professor W H Tytler

The clinicians of the centres met periodically as a working subcommittee under the chairmanship of Dr Geoffrey Marshall, so also did the pathologists under the chairmanship of Dr R Cruickshank. Dr Marc Daniels, of the Council's scientific staff, was responsible for the clinical co-ordination of the trials, and he also prepared the report for the Committee, with assistance from Dr D A Mitchison on the analysis of laboratory results. For the purpose of final analysis the radiological findings were assessed by a panel composed of Dr L G Blair, Dr Peter Kerley, and Dr Geoffrey S Todd.

### Introduction

When a special committee of the Medical Research Council undertook in September, 1946, to plan clinical trials of streptomycin in tuberculosis the main problem faced was that of investigating the effect of the drug in pulmonary tuberculosis. This antibiotic had been discovered two years previously by Waksman (Schatz, Bugie, and Waksman, 1944), in the intervening period its power of inhibiting tubercle bacilli *in vitro*, and the results of treatment in experimental tuberculous infection in guinea-pigs, had been reported, these results were strikingly better than those with any previous chemotherapeutic agent in tuberculosis. Preliminary results of trials in clinical tuberculosis had been published (Hinshaw and Feldman, 1945, Hinshaw, Feldman, and Pfuete, 1946, Keefer *et al*, 1946), the clinical results in pulmonary tuberculosis were encouraging but inconclusive.

The natural course of pulmonary tuberculosis is in fact so variable and unpredictable that evidence of improvement or cure following the use of a new drug in a few cases cannot be accepted as proof of the effect of that drug. The history of chemotherapeutic trials in tuberculosis is filled with errors due to empirical evaluation of drugs (Hart, 1946), the exaggerated claims made for gold treatment, persisting over 15 years, provide a spectacular example. It had become obvious that, in future, conclusions regarding the clinical effect of a new chemotherapeutic agent in tuberculosis could be considered valid only

if based on adequately controlled clinical trials (Hinshaw and Feldman, 1944). The one controlled trial of gold treatment (and the only report of an adequately controlled trial in tuberculosis we have been able to find in the literature) reported negative therapeutic results (Amberson McMahon and Pinner, 1931). In 1946 no controlled trial of streptomycin in pulmonary tuberculosis had been undertaken in the USA. The Committee of the Medical Research Council decided then that a part of the small supply of streptomycin allocated to it for research purposes would be best employed in a rigorously planned investigation with concurrent controls.

The many difficulties of planning and conducting a trial of this nature are important enough to warrant a full description here of the methods of the investigation.

### Plan and Conduct of the Trial

#### Type of Case

A first prerequisite was that all patients in the trial should have a similar type of disease. To avoid having to make allowances for the effect of forms of therapy other than bed-rest, the type of disease was to be one not suitable for other forms of therapy. The estimated chances of spontaneous regression must be small. On the other hand the type of lesion should be such as to offer some prospect of action by an effective chemotherapeutic agent for this reason old-standing disease and disease with thick-walled

cavities should be excluded. Finally the age group must be reasonably limited, since the total number of patients in the trial could not be large.

Such closely defined features were considered indispensable, for it was realized that no two patients have an identical form of the disease, and it was desired to eliminate as many of the obvious variations as possible. For these several reasons the type of case to be investigated was defined as follows: acute progressive bilateral pulmonary tuberculosis of presumably recent origin, bacteriologically proved, unsuitable for collapse therapy, age group 15 to 25 (later extended to 30).

The selection of this type of disease constituted full justification for having a parallel series of patients treated only by bed-rest, since up to the present this would be considered the only suitable form of treatment for such cases. Additional justification lay in the fact that all the streptomycin available in the country was in any case being used, the rest of the supply being taken up for two rapidly fatal forms of the disease, *miliary and meningeal tuberculosis*.

#### Recruitment and Admission of Cases

Co-operation in the trial was obtained in the first place from Brompton Hospital (drawing on London County Council cases), Colindale Hospital (London County Council), and Harefield County Hospital (Middlesex County Council). The LCC and the MCC gave full co-operation, permitting recruitment of suitable cases from the areas served by them, covering a population of nearly six million persons. Accordingly letters were sent, through the tuberculosis departments of these authorities, to tuberculosis officers and to medical superintendents of general hospitals outlining the proposed trial and asking that particulars and x-ray films of possibly suitable patients be sent to the co-ordinator of the trials for consideration. Visits were paid to the tuberculosis clinics and hospitals to show by representative x-ray films the type of case sought and to explain in detail the nature of the controlled trial. When cases were submitted the clinical particulars and x-ray films were taken to the Committee's selection panel for consideration. When a patient had been accepted as suitable, request was made through the local authority for admission to one of the streptomycin centres, in spite of long waiting-lists these patients were given complete priority, and the majority were admitted within a week of approval.

The first patients to be accepted were admitted to the centres in January 1947. At first the impression was that cases of the type defined are seen often. In fact, such cases are not common. As it became evident after three months that enough cases could not be found in the London and Middlesex areas, other authorities were approached. The Welsh National Memorial Association, the Department of Health for Scotland, and the Leeds Tuberculosis Service made available centres at Sully, Bangour, and Killingbeck, and cases were recruited to those centres from the respective areas. In addition, another centre was opened in the London area, at the Northern Hospital (LCC).

By September, 1947, 109 patients had been accepted, and no more were admitted to this trial. Two patients had died within the preliminary observation week, these are excluded from the analysis. Of the remaining 107 patients 55 had been allocated to the streptomycin group and 52 to the control group.

#### The Control Scheme

Determination of whether a patient would be treated by streptomycin and bed-rest (S case) or by bed-rest alone (C case) was made by reference to a statistical series based on random sampling numbers drawn up for each sex at each centre by Professor Bradford Hill, the details of the

series were unknown to any of the investigators or to the co-ordinator and were contained in a set of sealed envelopes, each bearing on the outside only the name of the hospital and a number. After acceptance of a patient by the panel, and before admission to the streptomycin centre, the appropriate numbered envelope was opened at the central office, the card inside told if the patient was to be an S or a C case, and this information was then given to the medical officer of the centre. Patients were not told before admission that they were to get special treatment. C patients did not know throughout their stay in hospital that they were control patients in a special study, they were in fact treated as they would have been in the past, the sole difference being that they had been admitted to the centre more rapidly than was normal. Usually they were not in the same wards as S patients, but the same regime was maintained.

It was important for the success of the trial that the details of the control scheme should remain confidential. *It is a matter of great credit to the many doctors concerned that this information was not made public throughout the 15 months of the trial, and the Committee is much indebted to them for their co-operation.*

By definition, cases accepted for the trial were unsuitable for collapse therapy, clinicians were therefore asked to adopt collapse therapy only if the course of the disease so changed that some collapse measure became indispensable and urgent. In the S cases collapse therapy was in fact never applied during the four treatment months. It was given to five of the 52 C cases during that period.

#### Observation and Treatment Period

Each patient was to remain in bed at the centre for at least six months, and the results were to be assessed on the clinical status at the end of that period. In addition to the usual hospital records, clinical observations were entered on standard record forms designed particularly for this trial, these forms provided for details of history, criteria of acceptance, examination on admission, monthly routine re-examinations with assessment of progress since last examination, observation of toxic reactions, temperature and treatment records, and finally a pathological record form. Instructions on required frequency of examinations were given.

Clinicians and pathologists' meetings were held during the trials to discuss the work as it proceeded. The co-ordinator visited centres and was constantly in touch with the clinicians concerned to discuss the progress of the trial and the problems arising. The working subcommittee of pathologists established the technical laboratory procedures, discussed the findings at intervals, and arranged for independent checking of sensitivity tests of tubercle bacilli and streptomycin levels in the blood.

#### Analysis of Results

The general trend of results during the course of the trial was followed through the monthly reports from the centres. The analysis of results up to six months after the patient's admission is presented here, it is based on information from the standard record forms completed for each patient and on the x-ray films which have been made available by the hospitals concerned.

The films have been viewed by two radiologists and a clinician, each reading the films independently and not knowing if the films were of C or S cases. One of the radiologists had been attached to a centre taking part in the trial, the other two specialists had not been connected with the trial in any way. There was fair agreement among the three at a final session they met to review and discuss

films on which there had been a difference of interpretation, and agreement was reached without difficulty on all films. The results of radiological assessment presented in the main analyses are the agreed results, but the separate reports and their differences are discussed under the heading 'Changes in Radiological Picture'.

### Condition on Admission

Each patient was under observation at a centre for at least one week before streptomycin treatment or observation proper for the trial started. Data in Table I reflect the condition on admission.

TABLE I—Condition on Admission

General Condition	S Group		Max. Evening Temp. in First Week*	C Group		Sedimentation Rate	C Group	
	S	C		S	C		S	C
Good	9	8	98-98.9° F (36.7-37.15° C)	3	4	0-10	0	0
Fair	17	20	99-99.9° F (37.2-37.75° C)	13	12	11-20	3	2
Poor	30	24	100-100.9° F (37.8-38.25° C)	15	17	21-50	16	20
			101° F (38.3° C)	24	19	51-	36	29
Total	55	52		55	52	Total	55	51†

\* Temperature by mouth in all but six cases. † Examination not done in one case.

Thirty patients (54%) in the S group and 24 (46%) in the C group were in poor general condition at the start of the trial, of these, 20 and 17 respectively were considered to be desperately ill. Twenty-four S patients (44%) and 19 C patients (36%) had during the preliminary observation week maximum evening temperatures of 101° F (38.3° C) or over. In 36 S patients (65%) and 29 C patients (56%) the sedimentation rate (Westergren 200 mm reading at one hour) was over 50.

These data reflect the fairly acute clinical condition of most of the patients, though obviously the clinical picture was far from uniform in the 107 patients admitted to the trial. The data show also that random distribution has equalized the groups, if anything, there are more severe cases in the S group. There were 22 men and 33 women in the S group, 21 men and 31 women in the C group.

### X-ray Classification

All cases conformed more or less to the type defined but within the possible limits of the definition there were wide variations. All films showed opacities representing extensive infiltration of apparently recent origin, where there was room for doubt the length of history was taken into consideration as evidence of the age of the lesions.

It was thought at first that gross cavitation should be excluded, but this view was abandoned, as many otherwise suitable cases had large cavities. Thirty-two of the 55 S cases and 30 of the 52 C cases showed large or multiple cavities in the film taken on admission (tomography was not used as a routine), it must be stressed, however, that from their radiological appearance these seemed to be of recent development and that the lesions predominating in the lungs were bronchopneumonic in type.

In 19 S cases and in 19 C cases there was radiological evidence of segmental atelectasis.

### Treatment

All S patients were given streptomycin\* by the intramuscular route. The dose was 2 g per day, given in four injections at six-hourly intervals. This dosage was adopted

\*The streptomycin used was in the form of the hydrochloride obtained from one American producer. For technical particulars of the product see article in *Lancet* 1948 1, 582.

following exchange of correspondence with Dr H C Hinshaw, of the Mayo Clinic, to whom the Committee is indebted for advice during the planning of the trial.

The original intention was to continue streptomycin treatment for six months. However, reports from observers in the U.S.A., and a growing impression in our own centres, indicated that the maximum effect of streptomycin was reached within the first three or four months, and it was therefore decided in July, 1947, to treat patients for four months only, but to continue observation to the end of six months from admission as for C patients. (One patient was treated with streptomycin for 6 months, 2 for 5½ months, 6 for 5 months, 5 for 4½ months, the remainder, 41 patients were treated for 4 months.)

Patients in both groups were on bed-rest during the period of the trial, and were allowed only up to toilet where the general condition allowed. As already indicated, although patients admitted were considered unsuitable for collapse therapy, it was agreed that when the course of disease had so changed that collapse therapy was strongly indicated such treatment should be given. In 11 C patients collapse measures (artificial pneumoperitoneum with phrenic paralysis in 10 cases, pneumothorax in one) were induced at some time during the six months—three in the third month of observation, two in the fourth month, two in the fifth and four in the last observation month. In seven of the 11 the course of the disease appears not to have been affected, in four there was deterioration before and improvement after induction of artificial pneumoperitoneum. Collapse therapy was induced in 11 S patients during the fifth or sixth month, in all but two the course of the disease was apparently unaltered.

### Results at End of Six Months

Four of the 55 S patients (7%) and 14 of the 52 C patients (27%) died before the end of six months. The difference between the two series is statistically significant; the probability of it occurring by chance is less than one in a hundred.

Assessment of condition at the end of the six-months period should be based on a judicious combination of changes in the radiological picture, changes in general condition, temperature, weight, sedimentation rate and breath-hold content of the sputum. We have not attempted a numerical evaluation of the relative importance of each of these, and changes in them will be reported in turn. Appreciation of the clinical effects of the drug have not been lacking in the many reports published within the past two years. So far as possible, the analysis in this report will deal with the more readily measurable data only.

The following preliminary analysis is based on changes in the radiological picture alone, this being in our opinion the most important single factor to consider, it will be seen later that in the great majority of cases clinical and radiological changes followed similar trends.

TABLE II—Assessment of Radiological Appearance at Six Months as Compared with Appearance on Admission

Radiological Assessment	Streptomycin Group		Control Group	
Considerable improvement	28	51%	4	8%
Moderate or slight improvement	10	18%	13	25%
No material change	2	4%	3	6%
Moderate or slight deterioration	5	9%	12	23%
Considerable deterioration	6	11%	6	11%
Deaths	4	7%	14	27%
Total	55	100%	52	100%

The overall results given in Table II (extracted from Table IX) show differences between the two series that leave no room for doubt. The most outstanding difference

is in the numbers who showed "considerable improvement" in the radiological picture—i.e., those for whom at the end of the six-months period there was a reasonable prospect of recovery. Twenty-eight of the S patients (51%) and only four of the C patients (8%) were considerably improved (the probability of such a difference occurring by chance is less than one in a million).

Results in men and women were similar, and need not be tabulated here. There was a higher mortality among males in both S and C groups, two of 22 male S patients died and eight of 21 male C patients, compared with two of 33 female S patients and six of 31 female C patients, but the difference is not significant.

### Results Related to Condition on Admission

The next point to be considered is whether the prognosis was worse in those most acutely ill, and whether the difference between the S and C groups applies to the less or more acutely ill patients.

#### Temperature

TABLE III—Results at Six Months Related to Temperature on Admission

Max Evening Temp during First Observation Week		Radiological Assessment at 6 Months			Deaths	Total
		Improvement	No Change	Deterioration		
98-98.9° F (36.7-37.15° C)	{S	3	0	0	0	3
	{C	3	1	0	0	4
99-99.9° F (37.2-37.75° C)	{S	9	1	3	0	13
	{C	7	2	2	1	12
100-100.9° F (37.8-38.25° C)	{S	13	0	2	0	15
	{C	5	0	7	5	17
101° F (38.3° C) +	{S	13	1	6	4	24
	{C	2	0	9	8	19

CHART I—Results at six months (radiological assessment) related to temperature on admission

The results in Table III, represented graphically in Chart I, show first what was to be expected—viz., in both groups the most grave prognosis was in the patients most febrile on admission: indeed, in the S group the only deaths

were in patients who had on admission evening temperature of 101° F (38.3° C) or over. A second, more important point that emerges is that the superiority of results in the S group as a whole over the C group is almost entirely accounted for by the most febrile patients. Only seven (19%) of 36 C patients with a temperature of 100° F (37.8° C) or over were improved at the end of six months, compared with 26 (67%) of 39 S patients. Further analysis reveals that eight of the 24 S patients with a temperature of 101° or over showed considerable improvement, and none of the 19 C patients. In less febrile and in afebrile patients there is little difference in results between the two groups, though analysis shows that the number showing considerable improvement was greater in the S group.

### Sedimentation Rate (ESR)

Relation of results to the ESR on admission shows the same trends. Of patients with an ESR not higher than 50, 13 (68%) of 19 S patients were improved, compared with nine (41%) of 22 C patients. Eighteen (50%) of 36 S patients with ESR over 50 were improved, compared with seven (24%) of 29 C patients.

### Radiological Assessment on Admission

TABLE IV—Radiological Assessment at Six Months Related to Presence or Absence of Gross Cavitation on Admission

X Ray on Admission	Group	Total Cases	Radiological Assessment at 6 Months					Deaths
			Improvement		No Change	Deterioration		
			Con siderable	Slight or Moderate		Slight or Moderate	Con siderable	
Cases with large or multiple cavities	S	32	11	7	2	4	4	4
	C	30	1	8	2	6	2	11
Other eases	S	23	17	3	0	1	2	0
	C	22	3	5	1	6	4	3

The data in Table IV show that in both S and C groups the results were better where there was no gross cavitation on admission. In the S cases with no gross cavitation the results were outstandingly good with no deaths and 17 of 23 patients showing considerable improvement.

### Clinical Changes During Period of Trial

#### General Condition

Assessment of changes in general condition is based on a combination of clinical facts, clinician's general impression, and patient's feeling of well- or ill-being. As such it is mentioned only briefly here. At four months after admission the general condition had improved in 40 (73%) of the 55 S patients, compared with 26 (50%) of 52 C patients. Only seven (13%) S patients were worse, whereas 10 (19%) C patients had died and another 13 (25%) were worse than on admission. At six months after admission the difference between the two groups was less, in 33 (60%) S patients and in 24 (46%) C patients the general condition was better than on admission. 13 S patients (24%) were worse and four others (7%) had died, 12 C patients (23%) were worse and 14 others (27%) had died.

#### Temperature

Three S patients and four C patients were afebrile on admission to the trial. The three S patients remained afebrile throughout, with the exception of a short slight pyrexial episode in one case. Two of the four C patients remained afebrile throughout, the other two had occasional low pyrexia, and one was still pyrexial at the end of the six

months Temperature changes in the febrile patients at two months, four months, and six months after admission are shown in Table V

TABLE V—Temperature Changes in Patients Febrile on Admission

Highest Evening Temp During Week following Admission	Group	Total	No. of Patients whose Temperature was Normal at end of			No. of Patients Showing Temp Fall (including Fall to Normal) at end of		
			2 Mos	4 Mos	6 Mos	2 Mos	4 Mos	6 Mos
101° F (38.3° C) or over	{S C}	24 19	1 0	5 2	6 3	15 7	14 6	11 8
99–100.9° F (37.2–38.25° C)	{S C}	28 28	8 5	15 10	18 10	12 10	19 11	24 12

\* Temperature for one C case not available

The difference between S and C series at any one point of time is not statistically significant, but appears at every stage—i.e., at every stage more S patients than C patients show a temperature drop to normal or to a degree of pyrexia lower than that on admission. A common effect of streptomycin not obvious in the above simplified presentation of data is a rapid temperature drop in the first weeks of therapy, followed sometimes by a rise to a level usually lower than the level on admission. Among the less acutely febrile patients (temperature 99–100.9° F, 37.2–38.25° C) an increasing number of S cases show falling temperature, at six months 18 of the 28 were apyrexial and six others had temperatures lower than on admission, 10 of 28 similar C cases were apyrexial and two others had temperatures lower than on admission.

There is thus a consistent difference between S and C groups. It is important to note, however, that in 20 of 47 febrile patients treated by bed-rest without streptomycin the temperature was lower at the end of six months than on admission, in 13 of the 20 it was within normal limits. For the type of lesions selected, these results serve to emphasize both the value of prolonged bed-rest and the need of controls in an investigation of this type.

In seven of the 13 C patients with normal temperature at the end of six months an artificial pneumoperitoneum had been induced at some time during the trial, but in every case the temperature had come down to normal previous to the induction of artificial pneumoperitoneum. The temperature fall in the C patients can be attributed to the effect of bed-rest alone.

Weight (Table VI)

In the first four months 20 S patients had gained weight (5 lb—2.27 kg—or more), with a total weight gain between them of 253 lb (114.76 kg), mean 12.6 lb (5.71 kg). The weight gains in the C group are very similar: 20 patients gained weight, with a total gain of 255 lb (115.67 kg), mean 12.7 lb (5.76 kg). At the end of six months 24 S patients had gained weight, with a total gain of 451 lb (204.57 kg), mean 18.8 lb (8.53 kg). Eighteen C patients had gained weight, with a total gain of 313 lb (141.97 kg), mean 17.4 lb (7.89 kg).

TABLE VI—Weight Changes

Weight Changes	4 Months After Admission		6 Months After Admission	
	S	C	S	C
14 lb (6.35 kg) or more gain	8	6	19	12
5–13 lb (2.27–5.89 kg) gain	12	14	5	6
Less than 5 lb (2.27 kg) gain or loss	15	9	12	10
5 lb (2.27 kg) or more loss	13	7	11	5
Deaths	0	10	4	14
Total*	48	46	51	47

\* Information not available for all cases some patients too ill to be weighed

These facts reveal, first, that many patients with a severe form of tuberculosis gained weight on treatment by bed-rest alone, indeed, 12 at the end of six months had gained a stone (6.35 kg) or more in weight. Secondly, the weight gains in the S group in the first four months were no greater than in the C group, and therefore do not reflect the important improvement observed in other respects, on the other hand, there was more weight gain in the last two months—i.e., after treatment had stopped. It is certain that some patients failed to gain weight, or gained little weight, during the course of streptomycin treatment, and this may be at least partly ascribed to the gastric disturbances, which were severe in a few cases and in others were mild but sufficient to reduce appetite and retard weight gain.

## Menstruation

In 10 of 32 female S patients and in 12 of 31 female C patients menstruation was normal on admission and remained normal. In nine S patients and 12 C patients amenorrhoea persisted throughout. In 11 S patients and seven C patients menstruation appeared at some time during observation and remained normal subsequently, in addition two S patients had a temporary return of menstruation.

## Sedimentation Rate

TABLE VII—Sedimentation Rate

ESR	Group	On Admission	At 2 Months	At 4 Months	At 6 Months
0–10	{S C}	0 0	0 1	6 2	17 4
11–50	{S C}	19 22	31 10	23 15	17 18
51+	{S C}	36 29	24 37	26 23	15 14
Deaths	{S C}	— —	0 2	0 10	4 14
Total*	{S C}	55 51	55 50	55 50	53 50

\* Totals do not correspond in all columns as results were not available in all cases

The data in Table VII show two main differences between groups S and C. If one takes into account the patients who died, in the C group the number of patients with a very high sedimentation rate (over 50) was never reduced, in the S group the number fell from 36 to 19 (including four deaths). Secondly, at six months in only four C patients had the ESR fallen to within normal limits, in the S group the corresponding number was 17.

## Changes in Radiological Picture During Period of Trial

After the close of the trial the chest radiographs of all patients were viewed, and changes assessed, by the three members of the radiological panel working separately. They were not told whether films were of patients from S or C series. Radiographs of each patient had been taken on admission and at monthly intervals subsequently. It was decided to make as simple an assessment as possible, reviewing progress at two-monthly intervals, each two-monthly film being compared with the film taken two months previously and with the initial film. Thus the comparisons on which report was requested were 0 with 2 (initial film with film two months after admission), 2 with 4, 0 with 4, 4 with 6, and 0 with 6. Assessments were required to fall under one of the five headings: "considerable improvement," "moderate or slight improvement," "no change," "moderate or slight deterioration," "considerable deterioration." A report "no change" might signify no appreciable change in the radiological picture or improvement in one part of the lung offset by deterioration in another.

So simple a classification invited difficulties, and these were soon evident. How should atelectasis be classified? Some films showed considerable clearing of infiltration concurrently with enlargement of cavities—radiologically they were both better and worse. The analysis in Table VIII shows the separate results of readings by the three assessors. Two most important readings have been chosen for this analysis: 0 with 4 (comparison of initial film with film four months after admission) and 4 with 6.

TABLE VIII—Comparison of Radiological Assessments by Three Assessors

Interval	Group	Total Cases	Assessor	Radiological Assessment				
				Improvement		No Change	Deterioration	
				Con- siderable	Slight or Mod		Slight or Mod	Con- siderable
Admission to end of 4th month	S	55	X Y Z	18 27 27	24 17 15	4 3 1	5 4 6	4 4 6
	C	42	X Y Z	0 2 3	11 10 8	4 11 8	18 10 15	9 9 8
End of 4th month to end of 6th month	S	51	X Y Z	2 5 3	17 18 12	11 10 11	15 8 19	6 10 6
	C	38	X Y Z	0 2 1	11 9 10	18 19 11	7 5 14	2 3 2

It can be seen from Table VIII that there was some disagreement among the three members of the panel, but the outstanding differences between results in S and C groups remain unaffected.

Where reports were identical they were adopted as the final agreed report. Where the reports on a case by the three members fell in two adjoining columns of the classification (e.g., "considerable improvement" and "slight or moderate improvement") the majority of two was taken as the final agreed report. In all other cases there was held to be disagreement. Thus in the comparisons between radiograph on admission and radiograph at four months there was agreement in 76 cases and disagreement in 21. In the comparisons between radiographs at four months and at six months there was agreement in 75 cases and disagreement in 14.

At a final session the three members of the radiological panel met for discussion and review of films on which there had been disagreement. After a short discussion it was agreed that changes in the prognosis for the patient should be taken as the base-line of assessment. In a comparison of two radiographs of a patient the question should be, judging from these films alone, Has the outlook for the patient become better or worse? On this basis the films in question were reviewed, and agreement was reached on all of them. The analysis which follows is based on the agreed results. The overall results under the five different headings are given for each of the three assessments 0 with 4, and 0 with 6 in Table IX and Chart II, and for each of the three assessments 0 with 2, 2 with 4, 4 with 6 in Table X and Charts III and IV.

It is evident that at every stage there is between the two groups a great difference in the course of the disease.

At two months 76% of S patients showed radiological improvement, and in 14% the improvement was considerable, only 6% of C patients were improved, and in none was the improvement considerable. Of C patients 4% had died and another 38% were worse than on admission, 11% of S patients were worse, and none had died.

From the end of the second month to the end of the fourth month the proportion of S patients who improved (65%) was slightly lower than in the first two months, the corresponding proportion of C patients (18%) was higher, but the difference between the two groups is marked. Considering the overall change in the first four months, 78% of S patients were improved and only 21% of C patients, in none of the latter and in 45% of S patients the improvement was considerable. Of C patients 19% had died and another 42% were worse than on admission, no S patients had died and only 14% had deteriorated.

The proportion of S patients who improved in the fifth and sixth months was again lower than before (34% compared with 65% in the third and fourth months and 76% in the first two months), this can be seen clearly in Charts III and IV. Of S patients 7% died in that period and another 31% deteriorated (the total 38% compares with 20% in the preceding two months and 11% in the first two months).

TABLE IX—Changes in the Radiological Picture

Interval	Group	Total	Radiological Assessment						Deaths					
			Improvement		No Change	Deterioration								
			Considerable	Slight or Mod		Slight or Mod	Considerable

	C	42	100%	1	2%	9	21%	17	41%	9	21%	2	5%	4

months), 10% of C patients surviving at four months died and another 26% deteriorated. Despite the setback in S patients in later months, the result at six months compared with the condition on admission shows, as we saw in the preliminary analysis, a remarkable difference between the two groups.

CHART II—Condition on admission compared with condition at two, four, and six months (radiological assessment)

CHART III—Changes in the radiological picture in succeeding two monthly periods: 0→2, admission to end of second month; 2→4, end of second month to end of fourth month; 4→6, end of fourth month to end of sixth month

CHART IV—Percentage of total patients admitted (not of survivors at beginning of each period) showing improvement in radiological picture in succeeding two monthly periods and in six months

It is of interest to analyse in greater detail the changes that occurred from period to period. The analysis in Tables XI and XII relates results in succeeding two-monthly periods.

TABLE XI—Radiological Changes in Succeeding Periods (S Cases)

Admission to End of 2nd Month	Total	End of 2nd Month to End of 4th Month			
		Improvement	No Change	Deterioration	Deaths
Improvement	42	31	6	5	0
No change	7	4	1	2	0
Deterioration	6	1	1	4	0

Improvement	36	17	12	7*	0
No change	8	1	1	5†	1
Deterioration	11	1	2	5	3
Total	55	19	15	17	4

\* One case had begun to deteriorate in the fourth month though the overall assessment 2→4 was improvement

† Two cases had begun to deteriorate in the fourth month though the overall assessment 2→4 was no change

Thirty-one of 42 S patients who improved in the first two months continued to improve in the third and fourth months but less than half of those who improved in the third and fourth months made further good progress subsequently. Nearly all S patients who deteriorated in the first months continued to get worse subsequently, only one of the six in the first two months and one of the 11 in the third and fourth months improved subsequently, the improvement in the latter case began only after induction of pneumopentoneum.

Considering now the 17 S patients who deteriorated and four who died in the fifth and sixth months, eight had been getting worse during the preceding two months, six more had shown "no change," and seven had improved in the preceding two months. These cases are analysed in detail later.

Analysis of radiological changes in the C group (Table XII) shows that here patients who improved did so much more slowly. Only three patients improved in the first two

TABLE XII—Radiological Changes in Succeeding Periods (C Cases)

Admission to End of 2nd Month	Total	End of 2nd Month to End of 4th Month			
		Improvement	No Change	Deterioration	Deaths
Improvement	3	0	2	1	0
No change	27	9	9	8	1
Deterioration	20	0	2	11	7
Total	50	9	13	20	8
End of 2nd Month to end of 4th Month	Total	End of 4th Month to End of 6th Month			
		Improvement	No change	Deterioration	Deaths
Improvement	9	2	7	0	0
No change	13	5	4	4	0
Deterioration	20	3	6	7	4
Total	42	10	17	11	4

months, and they did not continue to improve subsequently. Nine patients showed improvement in the third and fourth months. In all nine the condition had been stationary in the first two months, the improvement was attributable to bed-rest alone—only one of these patients had collapse therapy, three and a half months after admission. None of the nine deteriorated in the fifth and sixth months, contrary to what was seen in the S group. On the other hand, as in the S group, nearly all patients who deteriorated in the first two months continued to deteriorate subsequently—i.e., for those who showed no response to the first two months of bed-rest and streptomycin, or bed-rest alone, the outlook was poor.

Six of the 10 C patients who improved in the fifth and sixth months received collapse therapy, in four of them the improvement was considered due to these measures.

#### Clinical Observations on Cases Showing Improvement

In the preceding sections various clinical and radiological changes have been analysed separately, the analysis showing for each factor differences between S and C groups. Below are additional data and some representative case histories to give a more complete picture of patients' progress under treatment.

##### Considerable Improvement in S Cases

Of the 28 S patients who radiologically had improved considerably at the end of six months 11 had been regarded as desperately ill on admission. All 28 improved from the first month of treatment. In none could the improvement even in later months be ascribed to collapse therapy.

(a) Twenty-one of the 28 improved clinically in all respects—i.e., their general condition and symptoms improved, they gained weight, temperature and ESR fell, 18 were afebrile at the end of six months, and 16 had gained more than 14 lb (6.35 kg) in weight. In eight cases the sputum had become negative to all examinations for tubercle bacilli.

Case 69—A man aged 25 had been ill for four months and had been in hospital since shortly after the clinical onset. Artificial pneumothorax had been attempted, but failed on complete bed rest throughout the four months he continued to deteriorate. On admission to the centre he was exceedingly ill, wasted, with laryngitis, with swinging temperature 99.4–103.4° F (37.4–39.7° C), sedimentation rate 66, sputum heavily positive. The chest radiograph showed confluent opacities of bronchopneumonic type throughout both upper and mid zones and scattered foci in the lower zones (Plate Fig 1). During the first two months there was slight clinical improvement, fever persisted though at a lower level, the sedimentation rate was unchanged, the sputum was negative on direct examination

and positive on culture. The chest radiograph showed little change. During the next months there was a striking turn for the better: symptoms regressed, the laryngitis improved, from the end of the fourth month he was afebrile, he gained 42 lb (19.05 kg) weight from the third to the sixth month (on admission he had been too ill to weigh). The sedimentation rate had fallen to 22. Sputum was still positive, though on culture only. Radiologically there was remarkable clearing of lesions (Fig 2).

Case 90—A woman aged 24 had been ill for two months, her condition had been aggravated by recent parturition and post-partum haemorrhage. She was in hospital for two weeks before admission to the streptomycin centre. She was desperately ill on admission, wasted, and had a pyrexia varying from 99 to 103.4° F (37.2–39.7° C), sedimentation rate 150. On the chest radiograph were dense confluent opacities throughout the left lung, with some cavitation and less extensive lesions in the right lung (Fig 3). She remained critically ill during the first week of treatment, after which there was marked improvement in her general condition and symptoms. The evening temperature fell to 100° F (37.8° C) at the end of the second month, and from the end of the fourth month she was afebrile. Weight gain was only 4 lb (1.8 kg). The sedimentation rate fell progressively to 20 at the end of six months. The sputum and material from gastric lavage were negative to all methods of examination for tubercle bacilli from the 59th day onwards. There was considerable radiological clearing of lesions (Fig 4). The result on discharge must be regarded as dramatic (report by clinical registrar).

(b) Seven of the 28 patients improved clinically in most respects but six were still pyrexial at six months, and the other, though afebrile, remained in poor general condition with no weight gain and a high ESR (Case 39, Figs 5 and 6).

##### Considerable Improvement in C Cases

Considerable improvement in the radiological picture was reported for only four C patients. None were acutely ill on admission. In none of them had the sputum become negative at the end of six months.

In Case 73 there was general clinical improvement beginning in the first month, but the marked radiological improvement dated only from the induction of artificial pneumoperitoneum three and a half months after admission. In Case 80 also there was improvement in all respects, but only after induction of pneumoperitoneum two and a half months after admission.

In the two others, Cases 81 and 96, the improvement was attributable to bed-rest alone. Both improved clinically but retained a low pyrexia.

Case 81—A woman aged 22 had a six-months history of illness, and had been in bed at home for six weeks. On admission she looked ill and wasted, and had a low pyrexia (97.4–99° F (36.3–37.2° C)) and a sedimentation rate of 110. Chest radiography showed scattered nodular shadows throughout both lungs, denser at the apices, with a large cavity in the upper zone (Fig 7). From the first weeks her general condition improved, and in the six months she gained 28 lb (12.7 kg). She retained, however, a low evening pyrexia, the sedimentation rate at the end of six months was 85, and the sputum was positive on culture. Radiologically there was considerable regression and shrinkage of lesions, and the cavity system in the upper zone was less obvious (Fig 8).

##### Slight or Moderate Improvement in S Cases

At the end of six months, of 10 S patients who showed radiologically slight or moderate improvement five were afebrile, four had sedimentation rates not above 10, and two had gained over 14 lb (6.35 kg) in weight. In none of the 10 cases was the sputum negative, though in two it had been negative at some time during treatment and was positive again later.

Case 95—A woman aged 25 was extremely ill on admission. She had a history of symptoms for about

months, and had been in bed at home for four weeks. On admission she had a temperature swinging between 99 and 102.4° F (37.2 and 39.1° C), and was very weak and wasted. The sedimentation rate was 28, the sputum heavily positive. There was extensive infiltration in the lungs, particularly in the right lung where there were large cavities, a calcified primary complex was clearly definable on that side (Fig 9). Clinically she made excellent progress throughout the six months, with remarkable improvement in the first two months of treatment, and she gained 28 lb. The evening temperature had fallen to 99° F (37.2° C) at the end of two months, and shortly after became normal and remained normal. The sedimentation rate fell to 5. The sputum was negative at four months, but subsequently was occasionally positive. Radiologically there was little change in the first two months and improvement subsequently, with clearing at the right base and cavities much less obvious at the right apex (Fig 10).

#### Slight or Moderate Improvement in C Cases

Of 13 C patients who showed slight or moderate improvement radiologically at the end of six months, eight had improved clinically in all respects, three of the eight had been clinically very ill on admission. In two the sputum became negative (in one of the two after artificial pneumoperitoneum). Ten were afebrile at six months, and six had gained over 14 lb. In most of these cases the clinical improvement was much greater than that seen in the lung radiographs.

*Case 66*—A man aged 23, ill for about six weeks, had been admitted to a general hospital as a case of appendicitis one month before his admission to the centre. His general condition was fairly good, symptoms were slight, the temperature ranged from 97.6 to 100.2° F (36.4 to 37.9° C), the sedimentation rate was 70. There was shadowing throughout the upper and mid-zones of both lungs, particularly dense and with cavitation on the left side (Fig 11). During the six months of observation there was slow but progressive overall improvement, he put on 24 lb (10.88 kg) in weight, symptoms improved, he was afebrile after the third month, three consecutive sputum specimens at the end of the fifth and sixth months were negative. Radiologically there was moderate improvement, with some shrinkage of lesions particularly on the right (Fig 12).

#### Deterioration in S Cases

(a) In six patients there was radiological deterioration in the first two months. In two of these (Cases 87 and 99) there was no clinical response to treatment, and they continued to deteriorate until death in the fifth or sixth month. Two others (Cases 22 and 40) continued to deteriorate radiologically, clinically there was temporary improvement in the general condition, but temperature and ESR remained high, one (Case 22) died in the fifth month. One (Case 16) continued to deteriorate radiologically (deterioration confined to one lung), but the temperature fell to normal limits, the patient gained weight, and felt much better until after treatment stopped, ESR remained high, over 70. The sixth of these patients improved subsequently in the opinion of the radiologists' panel, but deteriorated clinically. Four of the six had gross cavitation on admission.

(b) In seven patients other than those just mentioned there was radiological deterioration through the third and fourth months. Five (Cases 46, 49, 60, 64, and 86) had improved radiologically in the first two months, and there had been temporary clinical improvement, in Case 60 there was marked clinical improvement until a spontaneous pneumothorax occurred three months after admission.

*Case 46*—A man aged 25 had been ill for six weeks with cough, dyspnoea, lassitude, loss of weight. He had been resting in bed at home for five weeks before admission to the streptomycin centre. On admission his condition was fair, his temperature ranged from 97.6 to 102° F (36.4 to 38.9° C), the

sedimentation rate was 40. Chest radiograph showed extensive scattered lesions in upper and mid-zones of both lungs and a large cavity in the left mid-zone. There was slight clinical improvement in the first two months of treatment, symptoms regressed, the temperature fell to a range of 97.8–99.4° F (36.55–37.4° C), the sedimentation rate was unchanged and weight was stationary. The clinical change was not of the same order as the change in the radiological picture, which showed considerable improvement (see Figs 13 and 14). During the third month the clinical condition was stationary except that the temperature began to rise again, and radiologically there was extension and more cavitation of the lesions in the left lung. He then began to lose weight (7 lb—3.18 kg—in the fourth month), to feel tired again, and radiographs showed further deterioration with extensive cavitation, a spontaneous pneumothorax occurred in the sixth month (Figs 15 and 16). The sputum had remained positive throughout, on the 65th day of treatment and subsequently strains of tubercle bacilli from the sputum were 8 000 times less sensitive to streptomycin than the strains isolated before treatment.

In the other two of the seven patients (Cases 54 and 105) the pulmonary condition was stationary radiologically in the first two months, one (Case 105) deteriorated clinically throughout the first months and until after induction of artificial pneumoperitoneum in the fifth month, after which there was radiological improvement also, the other was slightly better clinically in the first months of treatment, but the radiological worsening was rapidly followed by clinical deterioration, and she continued to go downhill. All seven of these cases which deteriorated radiologically for the first time in the third and fourth months had gross cavitation on admission, and five also had some atelectasis.

(c) Three other patients (Cases 11, 26, and 59) on whom the radiological report for the second two-month period was "no change" or "improvement" had begun to deteriorate radiologically in the fourth month—i.e., before treatment stopped. In Case 26 spontaneous pneumothorax was diagnosed in the fifth month. In Cases 26 and 59 clinical deterioration also began in the fourth month, in Case 11 only in the sixth month, after a haemoptysis. All three continued to get worse in the last months. Case 59 was the only one of these to have gross cavitation on admission.

(d) In nine cases radiological deterioration did not occur until the last two months. In three of these (Cases 28, 77, and 101) the radiological report for the third and fourth months was "no change", two of them had improved in the first two months, but at the end of the fourth month all three were still febrile and had a high ESR. In Case 28 the temperature fell to normal in the first two months and the patient gained 11 lb (4.98 kg) in weight, but the temperature rose in the third month, and there was subsequently continued clinical deterioration.

Finally, radiological deterioration in the fifth and sixth months was seen in six patients who had improved radiologically to the end of the fourth month. In two of these (Cases 7 and 24) there had been little or no clinical response to streptomycin treatment, at four months they were pyrexial, had lost over a stone in weight, and had a high ESR, both had gross cavitation on admission. The others (Cases 1, 4, 29, and 71) had improved clinically to the end of the fourth month, though at that date three were still pyrexial and none had an ESR below 40. Only one of these four had gross cavitation on admission.

*Case 1*—A woman aged 24, had been ill for about 10 weeks, and for six weeks before admission had been in bed at home. She was very ill when admitted, pale, wasted, with severe dyspnoea and lassitude, the temperature ranged from 100 to 104.2° F (37.8 to 40.1° C), the sedimentation rate was 98, the sputum was strongly positive. The chest radiograph showed

extensive shadowing of bronchopneumonic type throughout both lung fields, more dense in the left lung than in the right (Fig 17). In the first month the temperature dropped to a range of 99-101 F (37.2-38.3 C) and remained at this level during the rest of the four months of treatment. In the first month also there was definite improvement both in symptoms and in general appearance and she gained 7 lb (3.18 kg) in weight. At the end of two months the sputum was negative to direct examination and culture, and radiologically there was some clearing of the lesions, especially on the right. In the third and fourth months she began to lose her feeling of well being, appetite deteriorated and she lost 5 lb (2.27 kg) in weight, sputum became again heavily positive (strains were 250 times less sensitive to streptomycin than strains isolated before treatment). Radiographs, however, showed further considerable clearing of lesions (Figs 18 and 19). After treatment was stopped she felt better for a short time, but in the sixth month the condition deteriorated, symptoms were worse, the temperature rose to the same level as on admission, and radiographs at the end of the sixth month showed increased cavitation in the left lung and fresh lesions in the right (Fig 20).

This analysis has shown that though 21 S patients deteriorated radiologically in the fifth and sixth months—i.e., at a time when no streptomycin was being given in most cases—there is much evidence of commencing deterioration or arrested improvement before the end of the fourth month. Only six of the 21 had been improving radiologically throughout the preceding two months, two of the six had lost weight, and five had remained pyrexial since admission. Moreover, it is noteworthy that in patients who received streptomycin for more than four months results were similar to those for patients treated for four months only, deterioration in the fifth and sixth months was seen in five of 13 patients treated for more than four months, compared with 16 of 42 patients treated for four months only. However, in one patient treated for five months deterioration started in the sixth month. While there is suggestive evidence in a few cases that deterioration was related to cessation of treatment, it is very probable that some factor other than this is responsible in the majority of cases that deteriorated.

Gross cavitation may be a factor in determining relapse after first improvement. Of 16 patients who deteriorated at some time after first improvement, 11 (69%) had large or multiple cavities on admission, of 30 patients who improved throughout, 14 (47%) had large or multiple cavities. The difference is not statistically significant.

Spontaneous pneumothorax occurred in four S patients. In Case 60 it occurred at three months, the patient had been much improved until then, but subsequently went downhill rapidly and died. In two other cases deterioration had begun before the pneumothorax occurred. At first the impression was that this was a particular risk in the S group, but pneumothorax occurred spontaneously also in three C cases.

### Toxicity

Toxic effects of streptomycin therapy were observed in many patients, but in no single case did they necessitate cessation of treatment. For this reason and because toxic effects of this antibiotic have already been fully described by other investigators—e.g., Veterans' Administration (1947)—they will be mentioned here only briefly.

By far the most important toxic effect was the damage to the vestibular apparatus. Giddiness was a frequent first symptom, it was noticed by 36 of the 55 patients, and first appeared on sitting up in bed or turning the head suddenly. It appeared usually in the fourth or fifth week of therapy, and persisted for periods varying from one week to several months. Spontaneous nystagmus or lateral vision was another frequent sign of vestibular disturbance, blurring of

vision was less common. Tests for vestibular dysfunction were not carried out in all centres with sufficient regularity and uniformity to permit analysis of grouped results, but it is possible to say that absence or reduction of caloric response was not found with the frequency reported in many American investigations, and that in some patients loss of response was temporary only. No standard functional tests at the end of treatment were performed, many patients are reported as having unsteadiness of gait, which improved gradually with visual compensation but remained a handicap in the dark. Possibly many of these patients retain a disability revealed in a dangerous ataxia on such occasions as walking downstairs in the dark, crossing a congested street, or walking in a moving train. It is highly desirable that standard tests be adopted for assessment of vestibular dysfunction.

No loss of hearing was reported, except for two cases of high-tone deafness. Many patients suffered from nausea and vomiting, symptoms which were often relieved by antihistamine therapy. Albuminuria and casts in urine, raised blood urea, pruritus and urticarial rash, eosinophilia, "yellow vision" after injection, and circumoral numbness are among other transient effects reported. All subsided spontaneously—i.e., without stopping treatment.

### Bacteriology

#### (1) Bacterial Content of Sputum

Sputum was tested by direct-smear examination and by culture, where there was no sputum, material from laryngeal swab and/or gastric lavage was cultured. Examinations were done on admission and again at intervals of not more than one month.

In Table XIII the results in the third month and at the end of six months are related to the results on admission. Results of direct smear are recorded as "strongly positive" where one or more acid-fast bacillus per 1/12 in (0.2 cm) field was seen or where the result was recorded as +++ or ++, "weakly positive" includes results with less than one acid-fast bacillus per field or results recorded as +. For one hospital where only direct-smear examinations were done, and where degrees of positivity were not recorded, positive results in both groups have been tabulated in column 1, "strongly positive", one C case and one S case (Nos 3 and 107), positive on admission and negative to

TABLE XIII—Presence of Tubercle Bacilli

Results on Admission	Total	Deaths	Results in Third Month			
			Direct Smear		Smear Negative Culture Positive	Culture Negative
			Strongly Positive	Weakly Positive		
S Cases						
Smear strongly positive	40	0	16	12	10	2
Smear weakly positive	11	0	1	3	1	6
Smear negative culture positive	3	0	1	0	0	2
C Cases						
Smear strongly positive	29	5	19	3	1	1
Smear weakly positive	17	1	6	8	2	0
Smear negative culture positive	4	0	1	1	2	0
Results at End of 6 Months						
S Cases						
Smear strongly positive	40	4	24	1	7	4
Smear weakly positive	11	0	3	3	2	3
Smear negative culture positive	3	0	1	0	1	1
C Cases						
Smear strongly positive	29	11	15	2	0	1
Smear weakly positive	17	3	4	7	3	0
Smear negative culture positive	4	0	0	1	2	1

direct examination (no culture) at six months, have been excluded from the analysis, another (Case 62) has been excluded because no results were recorded for the third month

Considering the results in the third month, one C case and 10 S cases were negative to all examinations for tubercle bacillus. Apart from these cases of "sputum conversion," six C cases and 23 S cases were positive at a lower level than on admission. The differences between the two series are significant. There is no doubt here of the pronounced effect of streptomycin on the tubercle bacillus.

The results at the end of six months also show a difference, though less marked, between the two groups, two C cases and eight S cases had become negative to all examinations. These final results signifying "sputum conversion" are based on repeated examinations, in most cases of sputum, the case with least satisfactory evidence had negative results from one gastric lavage and two laryngeal swabs. Besides these cases five C cases and 10 S cases were at six months positive at a lower level than on admission. Taking together cases becoming negative or positive at a lower level, the difference between the two series is significant.

In the S group the results are best in cases without gross cavitation, six of 23 became negative, compared with two of 31 cases with large or multiple cavities.

If in order to get an overall evaluation of changes we give a numerical score to each category of results (4=negative, 3=smeared negative, culture positive, 2=smeared weakly positive, 1=smeared strongly positive, 0=death) the total in each group is as follows:

	On Admission	During Third Month	At end of Six Months
S cases	71	124	98
C cases	75	69	62

In the S group these results confirm the impression already gained of maximum improvement in the first months and subsequent deterioration.

The following numerical scores on the same basis are obtained from data for 51 of the S group analysed in greater detail (examinations for the C group were not frequent enough to provide comparable data):

Months after Admission	0	1	2	3	4	5	6
Bact. score	66	111	115	127	105	104	94

This overall evaluation shows the marked improvement during the first three months, followed by a steep fall in "score" in the fourth month and further decline later.

## (2) Streptomycin Sensitivity

Strains from 42 cases were tested for streptomycin sensitivity on primary isolation and during the course of treatment. Details of the technique adopted will be given in a subsequent report by the Pathological Subcommittee.

### A Degree of Sensitivity

All strains isolated before streptomycin therapy was begun showed sensitivity to the drug equivalent to that of the standard strain H37Rv (obtained from the American Depot, Trudeau Sanatorium, Saranac Lake), this was usually at a level of 0.1 to 0.5  $\mu$ g per ml, using the Tween-albumin medium.

**Sensitivity after Start of Streptomycin Treatment**—(1) In one patient (Case 90) there was not full opportunity to detect streptomycin resistance as all cultures were negative after the 59th day. (2) In six cases resistance did not emerge at a level above

10 times that of H37Rv. (3) In five cases strains were isolated which showed streptomycin resistance from 32 (one case) to 64 times (four cases) that of H37Rv. (4) In 17 cases resistance between 100 and 256 times that of H37Rv was demonstrated. (5) In 13 cases the resistance demonstrated was more than 2,000 times that of H37Rv, in four of these it was over 8,000 times.

Summarizing, strains with resistance over 10 times that of H37Rv were found in 35 of the 41 cases.

### B Time of Emergence of Streptomycin Resistance

In the majority it was not possible to detect with any great precision the date at which resistant strains could be first isolated, as specimens were not taken at frequent enough intervals. The date is taken as that midway between the date of the last sensitive culture and the date of the first resistant culture. In a few cases this interval was only a few days, in one it was 5½ months. Where it was possible to isolate strains at frequent intervals, it was seen that resistance rose rapidly to a maximum level at which it persisted subsequently with only minor fluctuations.

CHART V—Showing date of emergence of streptomycin resistance (over 10 times that of H37Rv)

The results are shown in Chart V. Of 35 cases showing resistance over 10 times H37, this resistance emerged in five cases in the first month, in 21 in the second month, four in the third, four in the fourth, and one as late as the fifth month. Taking all observations, the mean date of

emergence of resistance is the 53rd day after starting streptomycin therapy. The median is the 45th day.

#### Results Related to Resistance Development

The results given in Chart VI raise an important point: the radiological results at six months compared with condition on admission seem to be related to the degree of

if among the cases with high streptomycin resistance there is a higher proportion of initially severe cases than in the others, as if so this might account for the worse prognosis. Six of the 13 patients from whom were isolated strains over 1,000 times more resistant than H37Rv were very acutely ill on admission (had high pyrexia and large or multiple cavities), compared with nine of the 28 other patients. The difference is small. Moreover, there is both in the patients very ill on admission and in the others the trend to bad prognosis with increasing levels of streptomycin resistance. Thus in those very ill on admission the proportion deteriorating was 0/2 where resistance was not more than 10 times H37Rv, 3/7 where it was more than 10 and not more than 1,000 times (one of the three died), and 6/6 where it was above 1,000 times (three of the six died). In the other patients it was 0/5 where resistance was not more than 10 times H37Rv, 2/14 where it was more than 10 and not more than 1,000, and 2/7 where it was over 1,000 times. However, while the trend to bad prognosis with increasing levels of drug resistance is seen in both groups, the trend is greater in the patients very ill on admission than in the others; there is a possibility of relationship between severe clinical condition and development of high degrees of streptomycin resistance. In conclusion, one can say that the results were outstandingly good in cases in which little or no drug resistance was demonstrated, but for the others it remains difficult to assess the relative importance and the interdependence of the two factors—clinical condition at start of treatment and degree of drug resistance developed during treatment.

CHART VI—Radiological assessment at six months related to degree of streptomycin resistance

streptomycin resistance found during observation. Of six patients from whom strains isolated did not show resistance greater than 10 times that of the standard H37Rv, all had improved at six months. Twenty-two patients developed streptomycin resistance over 10 and less than 1,000 times H37Rv, five of them, or just under 1 in 4, had deteriorated at six months (one of the five had died). Of 13 patients in whom the drug-resistance developed was over 1,000 times H37Rv, eight or over one-half had deteriorated (three of the eight had died). The differences in results in the three groups are statistically significant.

If we consider not only the result at six months but deterioration at any time during the six months, it is interesting to note that the six patients who did not develop resistance over 10 times H37Rv improved throughout, without setback at any time in the six months.

Of the 22 cases with resistance 32 to 256 times H37Rv, deterioration occurred in six in the fifth and sixth months after continuous improvement in the first four months (but only two of these were worse at the end of six months than on admission), in two deterioration began after two months improvement, one began to deteriorate in the third month, the condition having been stationary in the first two months, one died after continuous deterioration throughout. The remainder, 12 patients, did not deteriorate at any time.

In the cases with resistance over 1,000 times H37Rv, deterioration began earlier: within the first two months in four cases, in the third and fourth months after initial improvement in three cases, and only in the final months in two cases.

Before accepting degree of streptomycin resistance as a major factor in prognosis it is important to determine

#### Discussion

This planned group investigation has demonstrated both the benefit and the limitations of streptomycin therapy in pulmonary tuberculosis. The trial—the first controlled investigation of its kind to be reported—was designed to give a negative or affirmative answer to the question, Is streptomycin of value in the treatment of pulmonary tuberculosis? It was not designed to determine in what types of pulmonary tuberculosis streptomycin could be effective, nor to determine optimal dosage or duration and rhythm of treatment.\*

Analysis of the results at the end of the first six-month period has shown that the course of bilateral acute progressive disease can be halted by streptomycin therapy, 51% of the streptomycin-treated patients showed considerable improvement radiologically when comparison was made with their chest radiographs taken on admission. That streptomycin was the agent responsible for this result is attested by the presence in this trial of the control group of patients, among whom considerable improvement was noted in only four (8%), and two of these four patients had improved only after collapse therapy. In other words streptomycin therapy was effecting what the patient's tissues alone could not do—checking the spread of the tubercle bacillus in one of its most favourable milieu.

Among the treated patients radiological improvement occurred most often in those who, though having extensive infection, did not have large or multiple cavitation. Nevertheless in one-third of those with gross cavitation considerable improvement also occurred, principally by resolution of recent infiltrative spread, some cases thus became suitable for collapse therapy. Streptomycin therapy alone did not lead to closure of large cavities.

The need of a control group in trials of a new drug for pulmonary tuberculosis is underlined by the finding that

\*Since this investigation was begun a number of notable publications on the effect of streptomycin in pulmonary tuberculosis have appeared. As, however, the prime objective of the Medical Research Council trial was a comparison of treated cases with controls, other investigations have not been referred to here.

impressive clinical improvement was seen in some of the patients treated by bed-rest alone 12 gained more than 14 lb (6.35 kg) in weight, and in 13 of 47 febrile patients the temperature was within normal limits at the end of six months. It was to be expected that in many of these patients with gross lesions who until recently had been at work the constitutional symptoms would be temporarily improved by bed-rest, although the lesions were so advanced that bed-rest alone could not be expected to effect corresponding improvement in the radiological picture. Nevertheless it should be noted that some radiological improvement was recorded in one-third of the C patients. The improvement in these patients was mainly among those least acutely ill on admission, and it is in this group that the treated series shows the least advantage over the control series. In such cases, with little or no pyrexia, relatively low sedimentation rate, and little cavitation, the patient's natural recuperative power added to bed-rest may in itself arrest the progress of the infection, and the advisability of using streptomycin in such cases may well be doubted. The major advantage is among the acutely ill patients. Although the only deaths that occurred in the S series were in this group, it is in these patients that the striking difference between the S and C series is most clearly demonstrated.

While stressing the good results in the streptomycin group, it is important to note, first, that no clinical "cures" were effected, and that only 15% were bacteriologically negative (to direct examination and culture) at the end of six months, and, secondly, that this trial presents at the time of writing only a short-term evaluation\*. The major improvement in patients treated with streptomycin was seen in the first two to three months, in the latter half of the six-month period numbers of them began to deteriorate. Thus 21 S patients deteriorated radiologically in the fifth and sixth months, and four of them died. Streptomycin therapy had been stopped at the end of four months, and it is natural to ask whether the deterioration is attributable to stoppage of treatment. This seems unlikely for the majority, most had begun to deteriorate radiologically before the end of four months, only six of the 21 had improved radiologically throughout the four months, and two of these six had deteriorated clinically.

Strains of tubercle bacilli resistant to high concentrations of streptomycin were isolated by the end of the second month of treatment from most patients whose sputum was still positive, this fact may account for at least a part of the deterioration witnessed in treated patients. Strains showing streptomycin resistance over 10 times that of the original strain or of the standard H37Rv were isolated from 35 of 41 patients for whom data are available, in 13 of the 35 cases the strains had a resistance over 2,000 times that of the control organism.

Therapeutic results appear to be related to the degree of drug resistance developed, thus the best results were seen in cases in which little or no drug resistance was demonstrated, and the worst results were in the group of 13 patients from whom were isolated strains of tubercle bacilli with a drug resistance over 2,000 times that of H37Rv. At the end of six months three of the 13 had died and five were radiologically worse than on admission. The relation between a bad prognosis and a high degree of streptomycin resistance applies particularly to patients most acutely ill at the start of treatment. The numbers involved are small, but the differences between the groups at different levels of resistance are suggestive. Probably both initial severity of clinical condition and development of drug resistance during treatment are factors responsible.

\*An addendum gives the results at one year after admission to the trial.

for deterioration, and the two factors may be interdependent. Even with the aid of a powerful chemotherapeutic agent healthy tissue reaction on the part of the host is necessary for complete destruction of the invading parasite. It is reasonable to suppose that, where a high degree of streptomycin resistance is demonstrable by the method used (which is qualitative and not quantitative), this may have occurred by rapid proliferation of resistant strains in tissues that have a poor natural defence against tuberculous infection.

On knowledge at present available, the development or emergence of streptomycin-resistant strains of tubercle bacilli is a fundamental factor to be taken into consideration when contemplating a course of streptomycin therapy. The technique of measuring sensitivity used in this investigation is so slow as to be of little immediate use in estimating, say at the end of one or two months of therapy, whether the course can be usefully continued or not. Organized investigations will be needed to determine whether emergence of streptomycin-resistant strains can be prevented by association of streptomycin with another drug or by a special rhythm of treatment. Until such time as this problem has been solved it seems fair to assume that after two to three months of streptomycin treatment in a patient with open pulmonary tuberculosis further treatment or a repeat course later is unlikely to be effective. Moreover, the possible dangers to the public health of dissemination of streptomycin-resistant strains, with the possible subsequent production of fresh cases (including cases of miliary or meningeal tuberculosis) which would not respond to streptomycin treatment, must be borne in mind.

One must add to this disadvantage of streptomycin therapy the information on the drug's toxic effects on the vestibular apparatus. These are frequent when the dose employed in this trial, 2 g a day, is given; recent American reports indicate reduced toxicity with a dosage of 1 g a day, but even then the effects are far from negligible.

These considerations must dictate a full measure of caution before prescribing streptomycin for any particular patient. They must be weighed in the balance against possible advantages of streptomycin therapy, particularly when contemplating its use for tuberculous lesions likely to improve by other known forms of treatment, and they render undesirable its administration for tuberculous lesions which, by reason of their age and pathological type, are unlikely to benefit by any form of chemotherapy.

The investigation reported here has demonstrated the value of streptomycin in one not very common form of tuberculosis. The type of result obtained indicates that the drug is probably of greatest value in cases of pulmonary tuberculosis in which the lesions requiring treatment are acute and of recent development. Its use may be recommended in acute contralateral spreads after artificial pneumothorax or after thoracoplasty. It probably has a place in the treatment of rapidly advancing pulmonary tuberculosis in which immediate collapse therapy would be dangerous or impracticable, in fact its most effective use may be in preparation of such lesions for collapse therapy. It has probably little place in the treatment of the more common chronic fibro-caseous forms of the disease. These conclusions are of necessity lacking in precision, much organized work is yet required to determine the precise indications of streptomycin and the best schemes of dosage in pulmonary tuberculosis.

#### Addendum

Before going to press it has been possible to collect data regarding the condition of each patient one year after admission to the trial. The data are based on a general

assessment by the clinicians concerned. Radiological evaluation by a panel was not possible, and therefore, although the data give a provisional impression of the course of the disease in these patients, the figures are not comparable with those based on independent radiological assessment, for example, in Table II.

TABLE XIV—Condition at 12 Months Related to Condition on Admission

Group	Total	Improvement	No Change	Deterioration	Death
S	55 100	31 56%	4 7%	8 15%	12 22%
C	52 100%	16 31%	5 10%	7 13%	24 46%

The difference in mortality between the two groups is statistically significant.

### Summary

One hundred and seven patients with acute progressive bilateral pulmonary tuberculosis, unsuitable for collapse therapy, were studied in a clinical trial of streptomycin.

The supply of streptomycin available during the investigation was limited. The type of disease selected was one considered hitherto unsuitable for any form of treatment other than bed rest. Bed rest accordingly was the treatment given to one group of 52 patients (C) while 55 patients were treated with bed rest plus streptomycin (S). Patients were assigned to one or the other group by random selection, and only after acceptance as suitable for the trial.

The period of observation for each patient, under conditions laid down for the trial, was six months.

S patients received 2 g of streptomycin intramuscularly daily in four injections at six-hourly intervals. No toxic effects necessitated stopping treatment, but vestibular disturbance was common.

At the end of six months 7% of S patients and 27% of C patients had died. Considerable improvement radiologically was noted in 51% of S cases and 8% of C cases. Slight or moderate improvement was noted in 18% of S cases and 25% of C cases. Apart from those who died, deterioration was seen in 18% of S cases and 34% of C cases.

The main difference between S and C series is among the patients clinically acutely ill on admission, thus among patients having on admission evening temperatures of 101° F (38.3° C) or over, 13 of 24 S patients and two of 19 C patients showed improvement radiologically.

More S patients than C patients showed clinical improvement, but the difference between the two series is smaller than in respect of radiological changes.

Improvement in S cases was greatest in the first three months. After the end of this period many S cases began to deteriorate.

At the end of six months examinations for tubercle bacilli were negative in eight S cases and two C cases. The best results in S cases were seen in the first months of treatment.

Results of tests for streptomycin sensitivity of infecting strains are given for 41 cases. In 35 cases tests revealed *in-vitro* resistance from 32 to over 8,000 times that of the original strain or the standard H37Rv. In most cases streptomycin resistance emerged in the second month of treatment. It seems probable that streptomycin resistance is responsible for much of the deterioration seen in S cases after first improvement.

An addendum gives the results at one year after admission.

The work of this investigation fell particularly heavily on the nursing staff and laboratory technicians of the centres concerned, and grateful acknowledgment is due to them for their assistance throughout the trials.

## SUDDEN DEATH DUE TO EPENDYMOMA OF CEREBELLO-PONTINE ANGLE

### REPORT OF TWO CASES

BY

N E FRANCE, MB, BCh

(From the Department of Pathology, Welsh National School of Medicine, Cardiff)

Sudden death has been described in many cases of sub tentorial tumours, but such an occurrence is almost invariably preceded by symptoms of raised intracranial pressure severe enough to induce the patient to seek medical advice some months before death. In the first case described here the patient gave a history of mild illness for only two days, whilst in the second case the patient continued at work until the day before his death. The presence of an intracranial tumour was not suspected during life in either case.

Bailey, Buchanan, and Bucy (1939) point out that sudden death may occur in cases of ependymoma of the fourth ventricle, but they describe such an occurrence only after lumbar puncture or manipulations of the head. Neither of these procedures was carried out in the present cases.

### Case 1

A girl aged 2 was in good health until two days before her death when she appeared unwell and was constipated. She was taken to her doctor, who prescribed an aperient, next day she was better and able to take her food satisfactorily. On the following day, however, she suddenly had a fit, made a choking noise, and died in a few minutes.

At necropsy a firm, pale, lobulated tumour with a smooth surface and crenated edge and measuring 4.3 by 3.7 cm was found on the inferior surface of the left lobe of the cerebellum, being related laterally to the medial surface of the left petrous bone. Superiorly the tumour reached and compressed the lower border of the pons and inferiorly the medulla and the upper part of the cervical cord were partially encircled and thrust towards the right. The tumour reached a point 4 cm below the lower border of the pons and 1.2 cm to the right of the midline. The left cerebellar hemisphere was compressed.

The left eighth cranial nerve ran into the mass, whilst the left vertebral artery, which lay on its surface was partially embedded in its substance. The whole was covered by the arachnoid mater, which could be moved freely over it. There was evidence of raised intracranial pressure with flattening of the convolutions of the cerebrum and bulging and thinning of the infundibulum, but the lateral ventricles appeared to be normal in size. No other lesions were found post mortem.

Histologically, the tumour had the appearance of an epithelial type of ependymoma (Fig. 1). The cells composing it contained round or oval nuclei showing rather coarse chromatin granules. Many of these cells formed canals with empty lumina lined by a single layer of cuboidal or columnar epithelium with basal nuclei, whilst others were arranged in rosettes around coils of cell processes. There was a complete absence of a basement membrane separating the rosettes from the surrounding stroma. The blood vessels were thin walled and in some areas the tumour cells were arranged around them, their processes extending to the vascular endothelium. The stroma consisted of a fibrillary network.

### Case 2

A boy aged 16 had suffered from headaches and occasional vomiting for two months but remained at work until the day before his death. He then complained of very severe headache and went to bed where he was found dead the following day.

necropsy a firm lobulated swelling, similar to that seen in Case 1, and measuring 6.2 by 4 cm, was found lying in the right cerebello-pontine angle on the inferior surface of the right cerebellar hemisphere. Superiorly it compressed the pons

FIG 1—Section from tumour of Case 1 showing epithelium lined canals ( $\times 210$ )

and extended over the right middle cerebellar peduncle to a point 0.8 cm above the lower limit of the pons, whilst inferiorly it passed through the foramen magnum and partially encircled the cervical cord, reaching a point 0.7 cm to the left of the midline. The tumour pressed upon the medulla, displacing it to the left, and compressed the right cerebellar hemisphere. The right vertebral artery lay between the tumour and the overlying arachnoid mater, whilst the right eighth cranial nerve was embedded in the substance of the mass. No other lesions were found post mortem.

Histologically (Fig 2) the tumour was much more cellular than that described in Case 1. The cells resembled astroblasts

FIG 2—Section of tumour from Case 2, showing typical rosette formation ( $\times 150$ )

but the nuclei were round or oval, with a coarse chromatin network. In many areas they were arranged in rosettes around coils of fibrils, sometimes with a thin walled blood vessel in the centre. In no parts could epithelium-lined canals be found. This is the histological picture of a cellular type of ependymoma.

## Comment

These two cases showed ependymomas of similar macroscopic appearance, Case 1 being of the epithelial type and Case 2 of the cellular type (Kernohan and Fletcher-Kernohan, 1937). Each tumour occupied one cerebello-pontine angle and exerted pressure on the pons, medulla, and cerebellum.

Ependymomas most often arise in the fourth ventricle, and their tendency to extend into the cerebello-pontine angle has been pointed out by Courville (1945). Having reached the basal cistern they may spread widely over the inferior surface of the cerebellum and around the medulla and cervical cord until their size is such as to cause pressure and give rise to symptoms. In a small percentage of cases sudden death may occur. When such a catastrophe as haemorrhage into a tumour occurs the cause of death is obvious (Wedd, 1942), but in the majority of cases of subtentorial tumours it is obscure.

Craig (1933) has stated that sudden collapse in patients with cerebellar tumours is usually due to respiratory failure and both he and Werden (1939) describe the successful removal, under artificial respiration, of such tumours when acute respiratory failure had occurred. On account of the anatomical positions of the neoplasms described in this paper, showing definite pressure upon the medulla and upper cervical cord, the addition of a moderate rise of intracranial pressure could easily precipitate acute respiratory failure. There is, however, no evidence in these cases of a definite cause for sudden raising of the pressure.

Grant, Webster, and Weinberger (1941) point out that convulsions are often seen in addition to the usual signs of raised pressure, and Webster and Weinberger (1940) conclude that these are due to cerebral anaemia.

It is possible that a sudden strain may in some way cause an increase of intracranial pressure great enough to give rise to a convulsion. It is perhaps significant that the only symptom of ill-health in Case 1 was constipation and this may have predisposed to the convulsion which immediately preceded death.

Typical cerebellar fits, characterized by head retraction, extended arms and legs, irregular pulse, and pyrexia with clouded consciousness, are believed to be due to compression of the bulbar centres (Bailey, 1933). It seems possible that such a fit was the explanation in these cases although usually there is a history of similar convulsions which become longer in duration and more severe until one finally ends in death.

## SUMMARY

Two cases of sudden death due to ependymomas in the cerebello-pontine angle are described.

Acute respiratory failure, cerebral anaemia with convulsions and cerebellar fits are discussed as possible causes of death.

I am indebted to Professor J. Gough for his criticism and permission to publish these cases and to Mr G. R. Armstrong and Mr J. P. Napper for their technical assistance.

# SKIN TESTS FOR SENSITIVITY TO LIVER

BY

P C REYNELL, MRCP

(From the Nuffield Department of Clinical Medicine Oxford)

It is well recognized that patients maintained on parenteral liver therapy may develop sensitivity to liver extract. Intradermal tests are usually employed as diagnostic aids in this condition, but there is a lack of uniformity in the interpretation of them. McSorley and Davidson (1944) recommend the use of 0.05 ml of undiluted liver extract and accept a weal of over 15 mm in diameter appearing in 15 to 30 minutes as a positive response, but they found that 16 out of 52 patients maintained on parenteral liver therapy were positive to a skin test although tolerating their injections without clinical reactions. Allin and Meyer (1940) observed weals in 13 out of 14 normal subjects given 0.05 ml of liver extract intradermally, and they suggest that only a weal with pseudopods should be accepted as a positive response. Other authors have observed that patients with clinical sensitivity to liver extract usually show a definite weal and flare after an intradermal injection of a 1 in 1,000 dilution of the extract (Feinberg *et al*, 1943, Bauer *et al*, 1947).

The present investigation was undertaken in order to try to assess the value of skin tests in the recognition of sensitivity to liver.

## Results

The cutaneous reactions of a group of patients undergoing maintenance treatment with liver injections were compared with those of a "control" group of patients suffering from a variety of diseases. The age and sex distribution of the two groups was strictly comparable, and the same highly purified extract of liver was used for therapy and for the intradermal tests.

All patients were given 0.05 ml of liver extract intradermally and the readings were taken after 10 to 15 minutes, since it was found in some cases that the weals tended to become less distinct after 15 minutes. It was impossible to record the results in quantitative terms, for the size of the flare was of little significance, the intensity and regularity of the weal seemed to be of greater importance than its actual diameter. The responses were therefore graded as follows: (1) a flare only, (2) a doubtful weal—i.e. a flare with raised central area which blanched when the skin was stretched, (3) a classical weal and flare, and (4) a weal with pseudopod formation. Definite weals were produced not only in 9 out of 11 patients receiving liver but also in 9 out of 11 controls, and the reactions were no more intense in those receiving liver (Table I).

TABLE I—Results of Tests with 0.05 ml of Liver Extract

	Intensity of Reaction			
	Grade 1	Grade 2	Grade 3	Grade 4
Control group	—	2	7	2
Patients receiving liver	—	2	8	1

Three separate groups of patients were then tested with serial dilutions of liver extract in normal saline. Each of these groups was subdivided into patients receiving liver injections and "normal" controls, but since there was no significant difference between these subgroups the results have been pooled in Table II. Definite weals were observed in 8 out of 14 subjects tested with a 1 in 10 dilution of liver extract, in 1 out of 26 tested with a 1 in 100 dilution, and in none of 17 tested with a 1 in 1,000 dilution.

TABLE II—Results of Tests with Dilutions of Liver Extract

Dilution	Intensity of Reaction			
	Grade 1	Grade 2	Grade 3	Grade 4
1 in 10	2	4	8	—
1 in 100	23	2	1	—
1 in 1000	16	1	—	—

While carrying out these experiments I have had the opportunity of doing skin tests on three patients with clinical manifestations of acquired sensitivity to liver. All three reacted with the formation of a definite weal when given 0.05 ml of a 1 in 100 dilution of liver extract, and in two of them weal formation was observed with a 1 in 1,000 dilution.

## Discussion

The diagnosis of acquired sensitivity to liver extract should be made mainly on clinical evidence. Skin tests are of secondary importance; they may show only approximate correlation with the severity of the symptoms (Bauer *et al*, 1947), and cases have been reported in which they were negative at the time of the first reaction and became positive later (Delikat, 1943, McSorley and Davidson, 1944). Positive reactions usually persist in patients who have been successfully desensitized (Feinberg *et al*, 1943), and this was observed in one of the cases recorded above.

There are patients, however, who describe vague and indefinite reactions after liver injections, and it is often difficult to know how much significance should be attached to their stories. In such cases the result of an intradermal injection of 0.05 ml of a 1 in 100 dilution of liver extract may be of considerable assistance in diagnosis.

**Conclusion**—Most normal people respond with a typical weal and flare to the intradermal injection of undiluted liver extract. It should not be concluded that a patient is sensitive to liver unless such a reaction is obtained with a dilution of purified extract of at least 1 in 100.

I am grateful to Professor L. J. Wits for his advice.

The Ministry of National Insurance states that in the first three months of the National Insurance Scheme 293,000 claims for maternity benefit have been made and that they are coming in at the rate of about 18,000 a week, but some mothers are losing money because they make their claims too late. The Ministry recalls that there are three kinds of maternity benefit. First there is a grant of £4 to help towards the usual expenses of having a baby. The grant can be claimed seven weeks before the birth is expected and must be claimed not later than three months after the event. Then there is an attendance allowance of £1 a week for four weeks after confinement for the additional help needed in the home during that time. It must be claimed within ten days of the birth. If the mother is not well enough someone else can claim for her and if necessary sign the form. The grant and the attendance allowance can be claimed either on the mother's own insurance or on her husband's, but not on both. To those mothers who have been in work or registering at an employment exchange over the year ending six weeks before they expect their baby a maternity allowance may be paid instead of the attendance allowance. This allowance is 36s a week for the 13 weeks beginning six weeks before confinement, provided that the mother gives up her work for this period. It should be claimed seven weeks before the week in which the baby is expected. If the claim is not sent in six weeks before the expected date of confinement, part of the allowance may be lost. Fuller details of these benefits and the conditions on which they are paid are given in Leaflet NI 17, and every expectant mother should get a copy from her maternity clinic. The leaflet can also be had at any local National Insurance Office, and inquiries about maternity benefit should be sent there.

## HEREDITARY HAEMORRHAGIC TELANGIECTASIA

BY

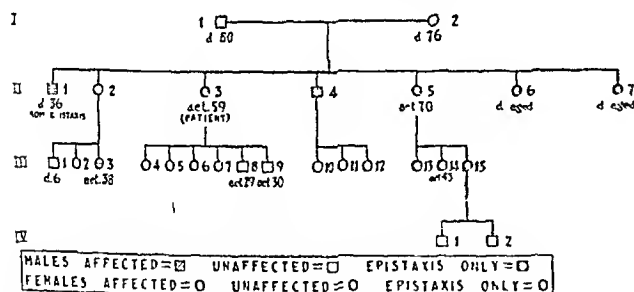

C P PETCH, MD, MRCP

Physician St Helier Hospital, Carshalton, Surrey

Hereditary haemorrhagic telangiectasia, sometimes known as the Osler-Rendu disease (Rendu, 1896, Osler, 1901), is a well-recognized but somewhat rare condition whose essential features are defined by its name. The characteristic lesions are telangiectases, or aggregations of dilated small vessels, initially minute but gradually increasing in size, scattered over the skin of the face and arms and the mucosa of the nose, mouth, and pharynx. They are also recorded as occurring at less usual sites such as the bronchial tree and the bowel. These defects are not present at birth but develop later, often in middle life. Their constituent vessels are formed by a single layer of endothelium and tend to bleed, most commonly in the form of recurrent epistaxis, to such an extent as to produce a severe microcytic anaemia or even death. Usually haemorrhage or anaemia brings the patient to the doctor. The familial incidence is very pronounced and is considered to show inheritance of the trait as a Mendelian dominant. The following pedigree is an addition to the available data.

### Case History

The patient (II 3), a woman aged 59, came to hospital feeling "run down." She was very pale and gave a history of repeated severe bleeding from the nose. Examination of the blood showed haemoglobin, 30% (Haldane), red blood cells, 3,570,000 per cmm, colour index, 0.4. No other abnormality was at first obvious, but, when her colour had been a little restored by the administration of iron, telangiectases were clearly visible on the face and arms, in the conjunctiva of the right eye, and in the mucous membrane of the mouth and nose. She stated that she had only recently noticed these spots but questioning revealed that three of her sisters (II 5, 6, 7) had similar facial blemishes. Two of these had died in old age, and

the third, aged 70, could not come for inspection. Her two brothers (II 1, 4) had severe epistaxis, one of them dying from this cause at the age of 36, which marks him (II 1) as a probable sufferer. The remaining sibling is unaffected. The patient's own six children do not yet show the condition, but since the eldest is only 30 they have time to develop it. Among her nephews and nieces a family of three sisters are all affected (III 13, 14, 15). One (III 13) has emigrated to Canada, where she is shown at clinical meetings as a case of a rare disease with "spots" on the face, presumably of the family complaint. Another (III 14) came to see me by invitation and showed typical telangiectases on the face and arms, but has not yet suffered from bleeding. The third (III 15) has not been able to attend but is said to have identical lesions. The descendants of the patient's unaffected sibling are also of interest. One (III 3) has severe epistaxis at the age of 38, another (III 1) died suddenly at the age of 6, bringing to mind the recorded instances of intracranial haemorrhage in early life in these families which have led some writers (Goldstein, 1921, Mekie, 1927) to postulate cerebral telangiectases.

### Discussion

Interest has been aroused in the haematology of this condition by Penfold and Lipseomb's (1943) report of a family in which hereditary haemorrhagic telangiectasia was associated with elliptocytosis of the red cells. Elliptocytosis is a feature of primitive marine vertebrates, and these authors put forward the interesting hypothesis that both abnormalities represent a harking back to an amphibian ancestor in which skin and oro-nasal mucosa have a respiratory function and are therefore highly vascular. I am indebted to Dr R H Trimick, of the South London Blood Supply Depot, for examining my patient's red cells for elliptocytosis, which he reports to be absent.

Another recent report (Singer and Wolfson, 1944) describes a family affected by hereditary haemorrhagic telangiectasia in which all three cases examined were unusual in having strongly positive tourniquet tests. This led the authors to regard the disease as one of a group of "capillary hereditary pathies," the other members being hereditary familial vascular purpura and pseudohaemophilia. In the present case the tourniquet test, as it is usually described, was negative.

A recent introduction in the therapeutic field—rutin—has been claimed as valuable in preventing bleeding from the telangiectases by virtue of its beneficial effect on capillary fragility. This substance is a flavone glucoside allied to hesperidin and derived from *Fagopyrum sagittatum*. It was tried in the present instance in doses of up to 40 mg three times a day for periods of a month at a time, but over a year there was no difference between the periods when rutin was taken and when it was not. Attempts at cautery of the nose have met with the usual rather disappointing results. Plugging has not yet been necessary, the use of oxidized cellulose gauze has been recommended in this connexion (Kennedy, 1947). In my patient an adequate blood count is being maintained (latest haemoglobin, 90%) by the administration of iron—one "fersolate" tablet thrice daily. She therefore represents the middle range of an abnormality the severity of which varies from complete harmlessness to a cause of early death.

The Ministry of Health, after consultation with the National Pharmaceutical Union and the Association of Executive Councils, has prepared a model scheme for testing the quality and amount of drugs and appliances supplied by chemists. It is proposed that England and Wales will be divided into six divisions, in each of which an analyst will work under contract with the executive councils in the division. Appliances will be tested by the Testing House of the Manchester Chamber of Commerce. When a test is to be carried out the clerk of the executive council will arrange for an official prescription to be written in duplicate and signed by a medical practitioner on the council's list, the practitioner will not be told the name of the chemist to whom the prescription is to be presented for dispensing. An agent of the executive council will present the prescription, and when it is dispensed he will tell the chemist that it is required for testing. The certificate of analysis given by the analyst or by the Testing House will be considered by the chairman or deputy chairman of the Pharmaceutical Service Committee and a registered pharmacist member of the committee. If they agree that no further action is required, the chemist will be informed that he may forward the prescription to the pricing bureau for pricing. If they consider that further action is warranted, the matter will stand referred to the Pharmaceutical Service Committee, which will investigate it as if a complaint had been made against the chemist in respect of an alleged failure to comply with his terms of service under Para 2 of Regulation 4 of the National Health Service (Service Committees and Tribunal) Regulations, 1948.

# INTUSSUSCEPTION IN ADULTS DUE TO CARCINOMA OF THE COLON

BY

R. A. C. OWEN, M.B., ChM., FRCS

Resident Surgical Officer, Walton Hospital, Liverpool

Intussusception in adults from any cause is rare, and cases due to carcinoma of the colon seem to be extremely rare. A search of the literature of the past 10 years reveals only two cases associated with a carcinoma of the colon. Rose (1945) described a case of intussusception of the descending colon due to a polypus with a near-by, but apparently unrelated, carcinoma of the colon. Iason (1945) described a case of intussusception of the transverse colon due to a carcinoma. Two further surveys dealing with this subject may be quoted to illustrate the rarity of the condition. Eliot and Corscaden (1911) collected up to that time 300 cases of intussusception in adults, only 20 being definitely due to carcinoma. Christopher (1936) could find only 10 cases of intussusception due to carcinoma since Eliot and Corscaden's paper. In view of this, and because they show other unusual features, the following two cases are recorded.

## Case 1

A woman aged 72 was admitted with a history of colicky abdominal pain, diarrhoea, and the passage of blood per rectum for the past two weeks.

On examination she was seen to be a thin frail old lady with evidence of recent loss of weight. There was no abnormality detected on abdominal examination. Rectal examination revealed a typical sausage-shaped intussusception which had almost reached the anal orifice, and hence a diagnosis of chronic intussusception of the large bowel was made.

**Operation**—Spinal analgesia was used. The abdomen was opened by a lower midline incision. An intussusception of the pelvic colon into the rectum was found. Reduction was, from the first, difficult, but was partially achieved with the aid of an assistant exerting pressure on the apex through the anal orifice. An impasse was then reached, as no further reduction seemed possible. On increasing the reducing force, signs of splitting of the bowel appeared and as no other means was possible the split was enlarged and complete reduction was achieved. It was now found that at the apex of the intussusception, in the middle portion of the pelvic colon, there was a small annular carcinoma. The split in the bowel was below this in the upper part of the rectum. The condition was further dealt with by excising the portion of the bowel containing the carcinoma and the split. Continuity could not be re-established and so the proximal end was brought out of the left inguinal region to form a permanent colostomy and the lower end was closed with two layers of sutures as in Hartmann's (1923) operation for removal of a carcinoma in the recto-sigmoid region. The rest of the abdomen was not explored because of the danger of disseminating septic material. The wound was closed without drainage.

Recovery was uneventful, and the patient was discharged on the 42nd post-operative day. The delay in her discharge was due to difficulty in obtaining a colostomy belt. The growth was reported as being a mucoid carcinoma. When last seen almost exactly two years after operation, she was in good health and without any evidence of recurrence of the growth.

## Case 2

A man aged 68 was admitted with a history of two weeks constipation, colicky abdominal pain, and the passage of blood per rectum.

On examination he was seen to be a well built man in fairly good general condition. Abdominal examination revealed considerable generalized distension and an increase in peristaltic sounds on auscultation. On rectal examination a typical intussusception with a papilliferous carcinomatous mass at the apex was found. It had reached as far as the lower part of

the rectum. A diagnosis of chronic intussusception of the large bowel due to a papilliferous carcinoma was made.

**Operation**—Spinal analgesia was used. The abdomen was opened through a right lower paramedian incision. It was found that almost complete reduction of the intussusception had occurred, the cause of this is discussed below. A small knuckle of bowel was still invaginated and reduction was completed easily. It was now found that the intussusception was of the pelvic colon, which was very mobile, and the papilliferous carcinoma could be palpated in its middle portion. There was no evidence of secondary deposits in the liver or peritoneum. The condition was dealt with by resection of the colon containing the carcinoma, together with about 24 in (62.5 cm) of normal colon on either side by Paul's method. The double barrelled bowel ends were brought out of a separate incision in the left inguinal region and Paul's tubes were inserted into the open ends.

Examination of the removed specimen showed a papilliferous carcinoma arising from an area about 1½ in (3.75 cm) in diameter in the middle of the loop of removed bowel. Microscopically it proved to be an adenocarcinoma.

Recovery was uneventful. The spur of the colostomy was crushed after an interval of three weeks, and the colostomy was finally closed at a second operation 10 weeks after the first. The patient was discharged 12 weeks after the original operation.

An interval of only seven months has elapsed since operation, but when last seen he was very well, with no evidence of recurrence. He had a slight tendency to constipation, but usually had a daily motion with the help of mild laxatives.

## Discussion

**Diagnosis**—This presented no difficulty in either case as the intussusception was easily palpable on rectal examination, in fact, in both cases it had nearly reached the anus. The presence of a carcinoma in Case 1 was not suspected until the abdomen had been opened and reduction of the intussusception had been completed. The carcinoma in Case 2 was readily palpable, and hence was diagnosed as the cause of the intussusception before operation.

**Methods of Operation**—As this condition is of necessity associated with a long and mobile pelvic colon, Paul's method of resection of the growth would appear to be satisfactory—as in Case 2—and is particularly useful in the old patient who would not stand a more extensive removal. It has the advantage of resection of the colon combined with a colostomy in one procedure, and continuity of the colon can be re-established later without any further major operation. This method could not be used in Case 1 because of the splitting in the region of the pelvic rectal junction, otherwise it would probably have been the method of choice.

**Results**—The unexpected good result in Case 1 was both surprising and gratifying. In spite of the inevitable peritoneal contamination convalescence was uneventful. It is unfortunate, however, that continuity of the colon could not be re-established. The partial reduction of the intussusception which occurred in Case 2 was an unexpected find at operation. The cause could not be determined with certainty, but was probably due to a series of enemata which the patient received before operation. If this is so it is interesting in view of the fact that this method of treatment of any intussusception has been advocated. It seems, however, that it could succeed only in intussusceptions of the distal colon.

I wish to thank Dr H. H. MacWilliam, medical superintendent of Walton Hospital, Liverpool, for permission to publish these cases.

## Medical Memoranda

### Two Unusual Cases of Abdominal Extrauterine Pregnancy

Two cases of abdominal extrauterine pregnancy are reported which were admitted to Mengo Hospital, Kampala, Uganda, within four months and present features worthy of record

#### CASE 1

The patient, a Muganda woman in the early twenties, had had a previous normal pregnancy. During antenatal observation the pregnancy appeared normal, the foetal position was left occipito anterior, the head above the brim of the pelvis, but a small hard mass low down on the right side of what was thought to be the enlarging uterus was noted and presumed to be a fibroid.

On April 15, 1946, when apparently at term, the patient was admitted to hospital, having taken a native drug popularly believed to induce labour. This drug, we have observed, usually causes abdominal distension and tonic contractions of the uterus. She appeared to be very ill and in severe pain, with a rapid pulse rate. The abdomen was distended and the uterus felt very hard and was tender. The foetal position was anterior and the foetal heart rate 120 a minute. The head was above the brim and the cervix was not taken up. She was treated expectantly with morphine. The pain decreased, and on April 29 the head was found to have entered the pelvis and was well below the mass felt on the right side. After a month, during which time she complained persistently of pain, the physical signs were unaltered. A medical induction on June 1 was unsuccessful. At her own request, and as her condition was deteriorating, laparotomy was performed.

At operation on June 5 the foetus was found lying free in an amniotic sac in the abdominal cavity. The presentation was cephalic in a completely occipito anterior position. Some exertion was needed to disimpact the head from the pelvis. The child, slightly post mature and weighing 8 lb 2 oz (3.66 kg), was delivered alive. The uterus was enlarged to the size of a 10 weeks pregnancy. Immediately after delivery there was a profuse haemorrhage from some detachment of the placenta, which was implanted on and received the majority of its blood supply from the ovarian pedicle and left Fallopian tube and was also adherent to the omentum and meso colon. The haemorrhage was temporarily controlled by a piece of rubber tubing used as a tourniquet around the base of the placental attachment. As much of the placenta was removed as possible but the membranes were left *in situ*. The abdomen was drained for 24 hours. The condition of mother and child was good next day, and they were discharged from hospital well some three weeks later.

It is clear that the initial error of diagnosis was caused by mistaking the fundus of the uterus for a fibroid. The position of the foetus being anterior, no limbs were palpable and the firm back felt like a uterus in tonic contraction. The pains must have been due to the 'false' labour described in these cases. The descent of the head into the pelvis was at the time unmistakable and supported the view that pregnancy was proceeding normally.

#### CASE 2

The patient was a Muganda woman aged about 20 on whom a caesarean section had been performed by one of us (W.R.B.) for disproportion. Following this she was febrile for the first few days of the puerperium and the wound in the perineum healed by second intention. The present pregnancy, her second, began about January, 1946, and was uneventful in the early months except for one week of peri umbilical pain in June.

On Aug 1 there was a sudden onset of pain in the morning and the patient was admitted to hospital the same afternoon. On examination a foetus was felt lying transversely. Pelvic measurements were small and the pains did not appear to be true labour pains. The patient was observed until Aug 10, when a membrane puncture with a Drew-Smythe catheter was attempted but only blood was obtained.

On Aug 14 a laparotomy was performed, as an extrauterine pregnancy was considered likely. On opening the abdomen a blood-filled bag of membranes presented, and on opening this a macerated foetus was extracted. A second bag was seen and a second foetus removed. The placentas and membranes were adherent to the under surface of the liver. The uterus had a rent on its anterior surface and was filled with blood clot and a subtotal hysterectomy was performed. The two umbilical cords were tied and cut short. The placentas were left *in situ*. One placenta was noted to be partially separated, and it was thought that the blood clot in and around the uterus was caused by blood draining by gravity from this placenta.

Penicillin was given and the patient made a good recovery. On Aug 30 a soft mass dull on percussion was noted on the left of the umbilicus. This gradually increased in size until on Sept 23 it almost filled the abdomen. It was freely movable and was not tender. There was no fever or leucocytosis. The patient left hospital on Sept 26, and when seen a month later the abdominal mass was unaltered and her condition good. She refused to undergo a further operation and has not yet been seen again. It was thought that the swelling was caused by autolysis of the placentas rather than infection.

Dr J. N. P. Davies, of the Medical Laboratory, Kampala, kindly reported upon the foetuses and the uterus, and stated that the male twin was smaller and lighter than the female. The male twin weighed 5½ lb (2.5 kg) and was 15 in (38 cm) in length. It appeared to have no abnormality, but examination was not complete before the twins were claimed by the father. The female twin was 17 in (43 cm) long and weighed 6½ lb (2.8 kg). The uterus measured 4 in (10 cm) from the cervix to the fundus and there was a tear down the anterior surface. The specimen was shown to Dr Gerald Holmes of Mulaga Hospital, and it was agreed that the tear in the uterus was of long standing and that it was the old caesarean operation incision which had failed to close. In between the pregnancies it would have been sealed over by the peritoneum, and the most probable sequence of events was that the developing ova were initially intrauterine and, either because of direct attack on the peritoneal covering or more probably because of rising pressure, broke through into the peritoneal cavity and became implanted upon the liver and spleen. Pregnancy then proceeded uneventfully until a partial separation of one placenta caused bleeding and abdominal pain on the date that the patient was admitted to hospital.

Our thanks are due to Dr J. N. P. Davies and Dr G. Holmes, of the Colonial Medical Service, for their advice and comments.

### Intravenous Procaine in Transfusion

The veins are innervated and their calibre is regulated in the same way as the arterioles, they constrict during pressor reflexes and dilate during depressor reflexes (Wright, 1945). Humble and Belyavin (1944) found that venous spasm occurring in shocked patients could interfere seriously with attempts at transfusion.

In cases of shock developing during operation the rate of flow of the intravenous drip transfusion may often be observed to become very slow, or it may even cease as a result of constriction of the recipient vein. On numerous occasions in such cases the administration of a solution of procaine hydrochloride by injection into the tubing of the transfusion apparatus near the needle has led to a great increase in the rate of flow, although neither the pressure of the transfusion nor the adjustment of the stopcock has been altered. This result is presumably due to a local action of the procaine in relaxing the constriction of the vein, for a prior control injection of a similar volume of normal saline does not produce the effect.

The amount of procaine hydrochloride usually employed is 5-10 ml of 1% solution, that such an amount may be safely administered intravenously has recently been shown by many workers (Lundy, 1942; Gordon, 1943; Allen, 1945). This injection may need to be repeated, as the duration of the effect varies from 10 minutes to an hour or more. Several examples are quoted in the Table.

Operation	B.P.	Rate of Drip Before Procaine	Rate of Drip 1 Min After Procaine
Laparotomy	95/60	36 per min	200 per min
For coarctation of aorta	110/60	100	270 "
Fractured skull	120/70	48	135 "
Combined excision of rectum	100/70	30	150 "
Repair of ventral hernia	100/60	40	250 +
Hemicolectomy	60/40	10	200 "

## Reviews

### HUMAN EVOLUTION

*A New Theory of Human Evolution* By Sir Arthur Keith  
(Pp 451 21s) London Watts and Co 1948

This book is a series of 41 essays, each more or less self-sufficient but grouped round the central notion that until the last 8 000 years or so the human species has consisted of small highly isolated groups, and that the instincts or mental biases making for such isolation have been a major factor in human evolution. This theory is not strictly new, and unfortunately Sir Arthur has not taken full cognizance of the extensive practical and theoretical work of Wright and his associates in America on the very different course which evolution takes in a wide ranging species as compared with one broken up into small groups. Nor does he refer to the researches of Dahlberg or the extent to which small groups are still reproductively isolated in rural Sweden. It is possible that he exaggerates the extent of the isolation between such communities. If the various tribes of Australia were fully isolated sexually the contour lines of blood group frequencies found in that country by Wilson Graydon Simmons, and Bryce would be quite unintelligible. Above all he may well be at fault in supposing that the competition between such units was primarily by war. One can wipe out a primitive tribe as effectively with infectious diseases as with machine guns. If I had to frame a theory of human evolution (which heaven forbid) I should lay very great stress on disease as a selective factor. Keith cites Vallois for the statement that 40% of Neanderthal skeletons are of individuals under 11 years old. Man could not live in dense communities till he had become able to resist crowd diseases to a great extent and immunological progress may have been important as moral and intellectual in rendering civilization possible.

Sir Arthur thinks that a 'dual code' of behaviour—amity to one's own group enmity to outsiders—is part of a man's nature, and that hence wars cannot be avoided. 'To the ethically minded, he states 'the dual code is anathema'. Now, I practise a dual code of sexual behaviour, one type being reserved for my wife the other for the remaining females of our species. My tomcat Puma has a unitary code, but if I imitated him I should be anathema to the ethically minded. Amity for one's own group need not imply hostility to others, and in fact many primitive tribes are hospitable to strangers while practising a fairly rigid endogamy. Nor do I murder or rob women to whom I am not married.

I agree with Sir Arthur that primitive communities may be regarded as evolutionary units, and completely disagree with his view that modern nations can be so regarded. A small tribe without any natural selection progresses half-way to complete homozygosis—i.e., loses half its heterozygosis—in a number of generations about equal to the number of breeding members in it. Thus a small tribe can become genetically homogeneous in a few thousand years, a nation could not in a hundred million. Moreover, most nations are extremely labile. We have only to consider the changes in the frontiers of Europe in the last 80 years to see that nations are not biological units and that it is most unlikely that they will last long enough to give rise to races, as Sir Arthur believes.

Unfortunately the essay on 'The Machinery of Evolution' is one of the weakest in the book. For example, the hypothetical population described on p. 127 has no mortality between the ages of 15 and 35. For an appreciation of recent work on this question the reader will do better to study such a book as Huxley's *Evolution*. On the other hand, in Essays 20 to 30 in which Sir Arthur discusses the actual history of human evolution he writes from very extensive knowledge. Whether or not the view put forward that man originated from *Australopithecus* or some related form and spread out from Africa be ultimately accepted it must be very seriously considered. Whether the major human races have evolved in parallel for as long as Sir Arthur believes may be doubtful but his arguments for his thesis are strong.

Nevertheless, I believe that one of the central theses of the book—namely, that "altruism signifies a complete abandonment of the evolutionary outlook" (p. 72)—is not only immoral but false. It may have been true in palaeolithic times, it is not true now. Those who practise altruism in our own society accumulate less money than the egoists. But the poor breed quicker than the rich. It is, as a matter of hard fact, the meek who inherit the earth. The same is true of nations. The Germans were persuaded by Hitler that a respect for other human beings was biologically unsound. They lost a great deal of population and territory as a consequence of this belief. So I hope and trust, will other nations which may imitate them in the future. The physician is bound to be somewhat of an altruist, and should realize that, by and large, altruism is not only ethically but biologically sound.

In spite of all these criticisms I can only close by stating that I shall congratulate myself if I can write as interesting and provocative a book as this at the age of 82. Even those who disagree most with it will find in it a wealth of information, particularly on the older literature of the subject and on recent human palaeontology, which will hardly be discovered elsewhere.

J B S HALDANE

### GASTRITIS

*Gastritis* By Rudolf Schindler, MD, FACP (Pp 462 96 figures £2 10s) London William Heinemann (Medical Books) Ltd 1947

This is a companion volume to the author's handbook on gastroscopy. It is written as a result of his experience since 1920 and is based on studies of more than 2,500 cases which were considered to be examples of uncomplicated gastritis. No one has done more than Schindler to paint a complete picture of gastritis, and his views will be studied closely in Britain where opinions which differ from his are widely held.

Schindler is aware of his critics and because of them he writes "Gastroscopy is a subjective method, the results obtained will and should be read with wholesome criticism, and only physicians who look through the gastroscope, not only occasionally, but often and routinely, will feel obliged finally to correct their laudable conservative attitude. Too few have time to do that. For that reason I have built this book around histopathologic pictures. Their study may convince the sceptic of the reality of the disease entity, chronic gastritis."

The pathological material was obtained at necropsy, from gastrectomy specimens, and in 15 cases from biopsies of the stomach wall during laparotomy for some other purpose. He discusses the results at length and illustrates them in nearly 100 photographs and photomicrographs. These undoubtedly show different appearances, but whether these are to be regarded as pathological variations or whether they come within the wide range of normality of the gastric mucosa is still subject for argument. In addition to the illustrations this important book contains a mass of evidence, argument and counter argument. The style is not always easy to follow but it must be studied carefully by physicians and gastroscopists as well as by morbid anatomists.

CHRISTOPHER HARDWICK

### TAYLOR'S MEDICAL JURISPRUDENCE

*Taylor's Principles and Practice of Medical Jurisprudence* Tenth edition Volume I Edited by Sydney Smith, CBE, MD, FRCP, Ed, DPH. With a complete revision of the Legal Aspect by W G H Cook LL.D., MSc (Econ) and of the Chemical Aspect by C P Stewart, Ph.D., MSc. (Pp 723, 48 illustrations £2 5s) London J and A Churchill 1948

Medical textbooks of to-day seldom attain the literary distinction which characterize the writings of the nineteenth century. The changing pace of life and more scientific method of study militate against it. It is the more remarkable therefore, that for some 85 years, through changing editorship, Taylor has retained its reputation as a work of forensic reference for its compass, authority, lucidity, and fine literary style.

Sydney Smith, who has guided its destiny for the last 20 years—longer than any previous editor—has moulded this new edition with great success. His remarkable experience in the subject and his ability in assessing the qualities of scientific

evidence have added appreciably to its value to the medico-legal specialist, and he has wisely retained so far as possible the pithy style and forthrightness of Taylor in the innumerable case histories which illuminate the text. Revision has been extensive *pari passu* with the advances in scientific knowledge and changes in statutory law, and it is unfortunate that the appearance of this first volume should take place at the moment when such a vast body of statute as the Workmen's Compensation Acts gives way to the improvements of the National Insurance (Industrial Injuries) Act, the legal editor, Cook, may find some remedy for this in the production of the second volume. Such a comprehensive and authoritative book of reference cannot afford to be without it.

It would be invidious for any reviewer to comb the text for what he might regard as omissions of detail, but Professor Smith's enthusiasm and vigour are capable of infinite effort, and we should like to see something of the encephalogram, of the psychiatrist's views on sadism and masochism in relation to both crime and accident on the identity of race from the skull, on explosive blast, the assessment of healed wounds—the newer work on *contre coup*, the physics of electrocution—so many mere trivialities on which he could discourse to our advantage. There is of course no end to such demands. Taylor remains a remarkably comprehensive volume of reference, authoritative lucid and in a literary style which maintains the best traditions of medicine.

KEITH SIMPSON

### MEDICAL PAPERS

*Anales de la Catedra de Clinica Medica* By Dr E S Mazzei  
Volume 1 (1946) (Pp 367, illustrated No price given)  
Buenos Aires 'El Ateneo' 1947

This volume is not easy to review, since it consists of a number of articles on unrelated subjects and a comprehensive survey would necessitate a dissection of each article in turn. Of the sixteen papers presented eight are about pulmonary embolism; they are written by Dr Mazzei in collaboration with two of his colleagues. They discuss the subject exhaustively, broadly classifying the cases into medical, surgical and obstetrical of which medical account for 25%, surgical 74%, and obstetrical only 1%. They consider treatment under three heads—prevention of venous thrombosis, prevention of emboli, and the measures to be taken once an embolus has occurred. Some of the prophylactic advice, such as abstinence from tobacco for ten days before operation, seems to be of doubtful value, some such as the condemnation of the classical Fowler position recalls recent controversy in Britain, most of it is thoroughly sound.

Among other papers in this volume there is a short but lucid one on the mechanics of obstructive emphysema and its relation to localized bronchial narrowing with consequent difficulty in expiration of air from the part of the lung distal to the partial block. Another paper distinguished by summaries in good Spanish, fair French and indifferent English is a review of modern concepts of functional renal insufficiency. The authors of the other papers each capably discuss a subject, although they may add nothing new; they maintain the general standard.

A MORTON GILL

The discoverer of streptomycin was the first in the field with a book on antibiotics written from a broad and philosophical rather than a clinical standpoint. The second edition of *Microbial Antagonisms and Antibiotic Substances* by Dr Selman A Waksman (London: Geoffrey Cumberlege 22s) is much expanded in scope and usefulness even though more still has happened since it went to press—chloromycetin for instance, one of the most promising of the latest discoveries, is not mentioned. As a soil microbiologist the author is at home in the greatest natural field of antibiotic activity and in an interesting chapter discusses the possibility of controlling plant diseases by introducing or encouraging micro-organisms as agonistic to plant pathogens in the soil. He presents in orderly form the mass of information which has been accumulated in the past few years about hundreds of antibiotic substances formed by various fungi and bacteria, the methods of detecting, extracting and studying them, and their chemical structure and biological activities. Few of these have attained the status of chemotherapeutic agents many never can owing to toxicity or other grave defects others have yet to be fully tested. To this remarkable new branch of science Dr Waksman's book is a comprehensive and useful guide.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Emergencies in Medical Practice* Edited by C A Birch, M.D., F.R.C.P. (Pp 468 25s) Edinburgh E and S Livingstone 1948

A manual of the treatment of medical emergencies

*Psychology and Mental Health* By C W Valentine M.A. D.Phil. (Pp 82 4s) London Methuen 1948

An exposition for the layman

*Everyday Problems of the School Child* By A H Bowley Ph.D. (Pp 142 7s 6d) Edinburgh E and S Livingstone 1948

A book for teachers and parents

*Andreas Vesalius Bruxellensis The Bloodletting Letter of 1539* By John B deC M Saunders F.R.C.S., and C D O Mallev (Pp 94 21s) London W Heinemann 1948

Translation of letter by Vesalius on phlebotomy, with annotations

*Minutes of the Dental Board of the United Kingdom* Vol 26 (Pp 99 No price) London Constable 1948

Also contains committee reports for 1947

*Tuberculosis in Childhood* By D S opford Price, M.D. and H F MacAuley, M.Ch., F.R.C.S.I. 2nd ed (Pp 219 2s) Bristol John Wright 1948

A general account of its epidemiology, symptomatology and treatment

*Infra Red Irradiation* By W Beaumont M.R.C.S., L.R.C.P. 3rd ed (Pp 161 8s 6d) London H K Lewis 1948

A manual of treatment with infra red rays

*Handbook of Medical Emergencies* By a group of Harvard medical students (Pp 106 14s) London Geoffrey Cumberlege 1947

Notes on the treatment of emergencies, intended particularly for students and house-men

*Problems of Fertility in General Practice* By M Hadley Jackson M.B. B.S., D.R.C.O.G. and others (Pp 255 17s 6d) London Hamish Hamilton 1948

The authors discuss sexual difficulties, the investigation and treatment of infertility, the prevention of repeated miscarriages and contraception

*Modern Methods of Infant Management* By W R F Collis M.A. M.D., F.R.C.P., F.R.C.P.I. D.P.H., and others (Pp 285 17s 6d) London Heinemann 1948

A practical manual on management of the newborn infant

*Adolescence* By C M Fleming, M.A., Ed B Ph.D., F.B.P.S. (Pp 261 16s) London Routledge and Kegan Paul 1948

An account of the mental development of adolescents

*First-Year Physiological Technique* By A Comfort M.B. D.Ch. (Pp 84 7s 6d) London Staples Press 1948

An introduction to technique in the physiology laboratory

*A Short History of Ophthalmology* By A Sorsby M.D. F.R.C.S. 2nd ed (Pp 103 8s 6d) London Staples Press 1948

A general history from earliest times

*Fever and the Regulation of Body Temperature* By E F DuBois M.D. (Pp 68 10s 6d) Oxford Blackwell Scientific Publications 1948

A monograph on the regulation of body temperature

*Disorders of Sex and Reproduction* By A P Pillay O.B.E. M.B., B.S. (Pp 299 18s) London H K Lewis 1948

The investigation and treatment of physiological and psychological disorders

*The Growth of a Profession* By J H Wickstead O.B.E., M.C.S.P. (Pp 212 6s) London Edward Arnold 1948

A history of the Chartered Society of Physiotherapists

STREPTOMYCIN IN PULMONARY  
TUBERCULOSIS

In few infections is it so difficult to assess the results of treatment as in pulmonary tuberculosis, with its varied clinical picture and unpredictable course. Remarkable recoveries can take place with no treatment except rest in bed. In the Medical Research Council's trial of streptomycin in pulmonary tuberculosis, the report on which is published in this issue, there was a satisfactory control series of patients, this made it possible for the first time to make a fair estimate of the effects of the drug in one form of the disease. The method of investigation is discussed in the next leading article. The trial was designed to do no more than answer the question, Is streptomycin of any value at all in pulmonary tuberculosis? Although no attempt was made to determine either the types of disease likely to respond most favourably or the most effective dosage of the drug, much valuable information beyond the limited scope of the inquiry has in fact emerged.

The type of disease chosen was "acute progressive bilateral pulmonary tuberculosis of presumably recent origin, bacteriologically proved, unsuitable for collapse therapy, age group 15 to 25 (later extended to 30)". The treated (S) cases received 2 g daily of streptomycin divided into four 6-hourly doses. Most patients were treated for four months, but some of the earlier ones for longer periods up to six months. The control (C) patients were treated by bed-rest alone in the same hospitals and with the same regime as the S cases apart from streptomycin administration. Although a few of the C patients became suitable for various forms of collapse therapy (artificial pneumoperitoneum with phrenic paralysis in all but one case) before the end of the observation period, these measures were not thought to have had an appreciable influence on the progress of most of them during the course of the trial. Both S and C cases were observed for a period of six months from the beginning of the investigation.

The results were analysed by changes in the radiographic appearances. These were assessed by a panel of three without knowledge of whether the films being viewed were those of S or C patients. The overall results leave no doubt of the beneficial effect of streptomycin. Of 55 S patients four (7%) and of 52 C patients 14 (27%) died within the six months. This difference is statistically significant. Of the S patients 27 (51%) and of the C patients four (8%) were judged radiologically to have improved considerably. Assessment of the changes in successive two-month periods showed that the improvement in S cases could often be seen during the earlier months, while the improvement in some of the C cases tended to occur later. Analysis of the results according to the degree of illness

of the patients on admission showed that the difference in response to treatment between the S and the C cases was very much greater in those patients who were more acutely ill with higher temperatures on admission to the trial. There was relatively little difference between the results in the S and the C patients whose maximum evening temperature during the first week did not exceed 99.9° F (37.75° C), the differences between the two groups as a whole being accounted for almost entirely by the more severely ill patients.

The extent of improvement in both S and C cases was greatest in those with no initial gross cavitation, of the 23 S patients without large cavities 17 improved considerably and none died. Streptomycin did not have a marked effect on the presence of tubercle bacilli in the sputum. Complete bacteriological information was available in 54 of the 55 S cases. Of these 54, four had died by the end of the trial, tubercle bacilli were found on direct examination of the sputum in 32 cases and by cultural methods in another 10. In only eight could bacilli not be found by any method, as compared with two of the C cases. There were no striking differences in the changes of weight between the two groups, in assessing the significance of this the gastric upset caused in many patients by the streptomycin must be taken into account. The condition of the patients in the two groups was reviewed by the clinicians in charge at the end of a year from the beginning of the trial. The differences between the two groups were then less evident than at six months. Twelve (22%) of the S cases and 24 (46%) of the C cases had died, while 31 (56%) of the S cases and 16 (31%) of the C cases had improved. The difference in mortality is statistically significant. The general impression derived from the study of the two groups is that the results from streptomycin treatment were best in those patients whose lesions were active at the beginning of treatment but had not yet formed cavities. Presumably these were the lesions which were truly of recent origin. When large cavities were present the results were not so good, and in less acutely ill patients the difference in progress between the S and the C cases was smaller.

The most important toxic effect was on the vestibular apparatus: giddiness was noticed by 36 of the 55 patients, usually in the fourth or fifth week of treatment. Nausea and vomiting occurred often, but these symptoms were often relieved by "benadryl". In no case did treatment have to be stopped because of toxic effects.

Complete information was obtained about the streptomycin sensitivity of the organisms isolated from 42 of the 55 treated patients. The sensitivity of all the strains isolated before treatment approximated to that of the standard H37Rv. In 35 of the 42 cases strains showing resistance 32 or more times that of H37Rv were isolated after treatment, in 13 of these the resistance was more than 2,000 times that of H37Rv. The time at which these resistant strains were detected was estimated as the midpoint between the times of isolation of the last sensitive strain and of the first resistant strain. The mean figure on this basis was the 53rd day after starting treatment. When frequent cultures were obtained it was found that resistance rose rapidly to a maximum level which was subsequently maintained. Comparison of the date of

appearance and degree of streptomycin resistance with clinical results brought out the fact that on the whole those patients from whom highly resistant strains were isolated early did less well than those whose organisms showed lesser degrees of resistance later. Seven patients whose organisms did not develop resistance over 32 times that of H37Rv improved steadily. The figures are not large enough to correlate the clinical results, the degree of streptomycin resistance acquired by the organism, and the other relevant factors such as the type of lesion present at the beginning of treatment.

This investigation has achieved its limited object by proving that streptomycin is of value in the treatment of acute forms of pulmonary tuberculosis. Many further problems remain to be solved, however, before the indications for the use of this new remedy in pulmonary tuberculosis can be regarded as firmly established. There are already enough favourable reports to justify the use of streptomycin in the treatment of ulcerative lesions of the main bronchi at the pre-stenotic stage where these are affecting prognosis. Its value in ulcerative tuberculous lesions of the larynx, pharynx, and tongue is also well established. Patients with old and apparently stable lesions who develop, while under observation, acute spread of the disease in previously unaffected parts of the lung may be expected to respond well, since they can be treated when the lesions are at the very earliest stage. Whether or not streptomycin should be used as a routine prophylactic against extension of the disease after surgical treatment for pulmonary tuberculosis remains to be seen. It is certainly of great importance to determine, for instance, whether streptomycin should be given prophylactically to patients undergoing thoracoplasty or whether it is better reserved for the treatment of the smaller number in whom the disease actually extends after operation. The answer to this question cannot be deduced *a priori*, even if patients treated prophylactically showed better immediate results, in the long run they might be worse off, since those among them who later had a recrudescence of disease suitable for streptomycin treatment might prove to be harbouring resistant organisms and to be no longer responsive to the drug. The question of the proper use of streptomycin as an adjunct to collapse therapy, both medical and surgical, must be settled.

Streptomycin resistance is perhaps the most important problem of all. From the point of view of the individual patient the probability that the organisms will develop resistance after a relatively short period of treatment means that a course of streptomycin may be effectual only once during possibly a long and chequered illness. From the point of view of the community there is the risk that patients with unsuitable lesions ineffectively treated may disseminate streptomycin-resistant organisms, so that an increasing number of new cases of all forms of tuberculosis may in future be found to be unresponsive to streptomycin. It therefore seems in the best interests both of the individual patient and of the community that streptomycin should be used for the treatment of pulmonary tuberculosis with a proper understanding of the difficulties and dangers and only when the indications for its use are clear. Streptomycin may, of course, be outmoded in the treatment of

tuberculosis by new and more potent antibiotics. Even so the enormous amount of work done upon it will not have been wasted. Laboratory and clinical techniques which have been evolved can no doubt be applied to the problems of other antibiotics, and the Medical Research Council's controlled trial will serve as a model for future investigations of substances introduced for the treatment of pulmonary tuberculosis.

## THE CONTROLLED THERAPEUTIC TRIAL

The clinical trial of a remedy is as old as medicine itself. The idea of controlled investigation and statistical analysis is recent enough to call new. With the older hit-or-miss method the patient was treated, and subsequent observation showed with what result. If the patient—or patients—died or at least failed to get well, the results that flowed from the remedy were unequivocal. It is when the patients, or anyway some of them, recover that we are faced with the *post hoc propter hoc* dilemma. Is the result due to the remedy or to the *vis medicatrix naturae*? Until quite recent years that difficulty was principally met—when it was met at all—by comparing patients submitted to the new treatment with the patients the clinician had observed in past years. The problems of such a comparison were many. It was often not certain that the patients selected for the trial were comparable with those previously seen. Those earlier patients were often not equally well documented, so that records were lacking and the comparisons necessarily crude, the numbers involved were frequently far too few to merit the confidence placed in them, and mortality from the same disease at different periods of time is affected by factors such as breeding out of highly susceptible stock, economic and social conditions, and variations in the infecting organism. With a new discovery that produces dramatic results there would rarely be any doubt about the answer, but such discoveries are rare. It is the smaller, yet often important, advances that it is difficult to substantiate—or disprove—by such rough-and-ready means. The meteoric rise and regrettably slower fall of many a form of treatment bear eloquent witness to the lack of the controlled trial in medicine. The application of such trials was gaining ground before the war and their value becoming more and more appreciated by the clinician—subject always, it must be stressed, to the fundamental ethical problem inherent in using human beings as the subject of experiment.

In developing the trial of streptomycin in the treatment of pulmonary tuberculosis, reported on page 769, the Medical Research Council's Committee was clearly relieved of this particular moral responsibility. It had allocated much of the limited streptomycin at its disposal to treating and observing two fatal forms of tuberculosis—the miliary and meningeal. It had, needless to say, a quite insufficient supply to treat all possible cases of pulmonary tuberculosis and in this situation rightly set about planning a rigorously controlled investigation. The plan adopted is worthy of careful study in itself, quite apart from the results to which it led, for it may well serve as a model in this field.

To begin with, the Committee was clearly of a mind not to dissipate its energies—and its small supply of the drug

in attempting to cover too wide or too ill-defined a field selected one type of case and defined it as rigidly as possible—recent progressive bilateral pulmonary tuberculosis of presumably recent origin, bacteriologically proved, unsuitable for collapse therapy, ages 15 to 30. In such trials it is often tempting to add little groups of patients of differing types here, there, and everywhere with the object of learning rather more. Though with a statistical design it will certainly sometimes pay to do so, very often the rather more becomes the rather less. Such a trial gives doubtful answers to the many points but no decisive answer to any. This temptation the Committee, and the clinicians co-operating with it, resisted.

Having defined the type of case it proposed to observe, the Committee next obtained the co-operation of various hospitals in carrying out the controlled trial and sought for suitable patients to place in their care. The important point here is that without some such central organization to direct the work, and without the collaboration of a number of hospitals in carrying it out, a sufficient number of patients of the same type will rarely be available. Small groups here and there will give conflicting answers. Then to ensure that the patient did conform to the features laid down the Committee set up a selection panel. This panel conceivably might have been influenced in selecting or rejecting a patient if it had known beforehand whether the patient was to be allocated to the streptomycin or to the controlled group—e.g., if alternate patients had been taken. It was relieved of any such worries by an ingenious system of sealed envelopes. Once a patient had been accepted an appropriate numbered envelope was opened, and not till then was the patient's group revealed. The allocation to "S" or "C" in this form had been made at random by the statistician. It is instructive also to see how close an equality of group characteristics this statistical method produced. For instance, 54% in the "S" group and 46% in the "C" group were in poor general condition at the start of the trial, 20 and 17 were desperately ill, 65% of "S" patients and 56% of "C" had a sedimentation rate over 50, 32 "S" and 30 "C" cases showed large or multiple cavities, in 19 of each group there was radiological evidence of segmental atelectasis. The random allocation has not only removed personal responsibility from the clinician and possible bias in his process of choosing patients, but has on the whole effectively equated the groups—fundamental, of course, to the general comparisons (the "S" group, as it happens, was slightly the poorer).

The hospitals to which these patients passed were provided beforehand with standard record forms designed specially for the trial, and examinations of the patient were required at fixed intervals. Thus uniform records were assured and any loss of essential particulars guarded against. Treatment was likewise standardized, though the clinicians in charge of the patients were naturally given freedom of action in urgent cases. To overcome any difficulties that might arise—indeed, were certain to arise in a trial of this nature—frequent meetings were held both of the clinicians and pathologists concerned, while the co-ordinator at the centre constantly visited the periphery. Clearly in this way much trouble was taken to ensure

smooth running and to develop a co-ordination of methodology in every respect throughout the hospitals. Finally the monthly reports from the hospitals were assessed centrally, and thus again uniformly. In this assessment it may be noted that one of the fundamental criteria of the effect of the drug was bound to lie in the change in the radiological picture. To remove all possibility of bias the Committee had the films assessed independently by two radiologists and a clinician, each of whom had no knowledge whatever whether the film they saw related to a streptomycin or to a control case. Such a method vastly increases confidence in the results, and it is important to realize that it in no way questions the intellectual honesty of the investigator who is thus asked to work "blind." It guards not only against unconscious bias but, equally important, against any honest attempt in the assessor to allow for a possible bias.

It was by these careful means that the Committee reached its objectives—a rigorously controlled investigation, an impartial assessment of its results.

## SOCIAL WELFARE AND VOLUNTARY ACTION

In his report on Social Insurance and Allied Services Sir William (now Lord) Beveridge told the Government of the day how the State could cure poverty by a comprehensive scheme of compulsory insurance. His new contribution to sociology<sup>1</sup> contains an account of the methods which have been used to alleviate misfortune. In effect he asks, Can the State, using all the means at its disposal, cure unhappiness? The answer is obviously No, even if we knew how to define happiness. A "good" society cannot be made without voluntary action for social advance even in what Lord Beveridge calls a Social Service State. He divides voluntary action into two categories, mutual aid and philanthropy. The best example of mutual aid is the friendly societies, which were established in order that men known to each other could pay money regularly into a common fund and draw on that fund when they were in need. But to the bulk of their 8,000,000 members in 1947 the friendly societies represented not good fellowship but a means of insurance by contract. In the first Beveridge report it was suggested that the friendly societies should be used as the agents of the Government for the distribution of State benefits to their members. Instead the marriage of 1911 between the State and the voluntary agencies has been followed by a divorce, and the State is now constructing a complete and exclusive administrative machine of its own.

Lord Beveridge gives some other examples of mutual aid societies, including the hospital contributory schemes, the growth of which he considers to have been one of the greatest successes of mutual aid in modern times. The need to provide for special expenses at death has been as widely felt as the need for security in sickness. From this grew the remarkable form of modern business known as industrial assurance. The Royal Commission which inquired into the work of friendly societies in 1871-4 did

not welcome this development, and it produced statistics to show that the insurance of young children's lives had led to increased mortality among the children insured. It therefore recommended that the insurance of the lives of children under 3 years of age should be prohibited altogether. When the national insurance scheme comes fully into operation it will be illegal to take out policies under which payments are made on the deaths of children under 10 years of age.

The philanthropic motive is defined as the desire by one's personal action to make life happier for others. The unobtrusive doing of good works is no longer a common occupation for the private individual. Certainly the basket of chicken broth and calves' foot jelly which, according to the Victorian novelists, the lady of the manor or the parson's wife took to the invalids in the village is a thing of the past. But, Lord Beveridge says, "democracy to-day has to show that in discarding the inequalities it can learn the virtues of aristocracy." There are fewer people than formerly with much leisure, but there are many more with a little leisure who might be willing to take part in some form of voluntary action. Among the more modern philanthropic organizations are the Nuffield Foundation and the King Edward Hospital Fund for London. How far organizations such as these have travelled from private charity can be judged by the fact that the income of the former for the year 1946-7 amounted to nearly £400,000.

The most difficult and perhaps the most rewarding of the problems which can be tackled by voluntary action is that of old age. It provides the best illustration of the needs which cannot be satisfied merely by providing a subsistence income. Old people should live in houses suitably planned for their needs, some require homes with service, and others, who are disabled by the diseases of old age, could enjoy life again if the "geriatric departments" suggested by the B M A committee<sup>2</sup> were set up in selected hospitals. Determined efforts must also be made to prevent sickness among the old.

The unhappy child is a pathetic and appealing figure, and for many years there have been charities concerned with the care of orphans and deserted children. Readers of this book will probably learn with surprise that the NSPCC had a hard struggle for recognition in its early days. The report of the Curtis Committee in 1946 showed that in spite of the efforts of charitable organizations and public assistance authorities the care of deprived children still left much to be desired. The field for voluntary action is wide, since deprived children include not only those without a home but also children who do not have a "normal" life at home because of the failings of their parents. Pity for the blind is widely felt, and there are at present 100 voluntary agencies looking after their welfare, they spend about £1,500,000 from private sources each year. The blind register kept by local welfare authorities, which shows where every blind person is who needs assistance, is the envy of blind-welfare organizations in other countries. There is no similar register of any other handicapped class in the community. The deaf do not receive the same statutory help as the blind, and Lord Beveridge describes the Government issue of free hearing-aids under the National Health Service Act as putting an end to the commercial

exploitation of the widespread demand for devices to improve hearing.

Much help is now given to disabled persons in the way of training and sheltered employment, but the Disabled Persons (Employment) Act does not meet all their needs. The register which the Ministry of Labour maintains is incomplete—it is a register only of disabled persons who seek employment. Those who wrongly judge themselves incapable of any work will probably not register. Other classes of the community who can be helped by voluntary action are unmarried mothers and children, discharged prisoners, and last but not least the tired housewife. Lord Beveridge praises the Lancashire Council of Social Service for its pioneer work in establishing the Brentwood recuperative centre for mothers and children.

In discussing how the needs of the physically and mentally disabled can be met by voluntary action Lord Beveridge does not refer to the powers now given to local health authorities by Section 28 of the National Health Service Act (Prevention of Illness, Care, and After-care). These powers are very wide, and important developments in public health practice will certainly be made when the authorities learn how to use them. Already after-care committees are asking what sort of local help can and should be given to the physically and mentally disabled. The highly trained professional social worker such as the health visitor and the local resident who is prepared to give a little of his or her spare time should between them be able to remove some of the unhappiness which is felt by the old, the disabled, and the lonely.

One of the most significant conclusions drawn from a study of the problems brought to citizens' advice bureaux was that "the material cause of unhappiness, quarrelling, and perplexity in Britain, outweighing all others in importance, was lack of enough buildings in which to live, meet, teach, learn, and do all else that is meant by civilized life." A result of shorter working hours has been that the businesses of football pools, dog tracks, and other entertainments are all now exploiting in different ways the increased spare time of people not taught how to use leisure. Lord Beveridge believes that these are matters which can be put right by voluntary action, the ultimate aim of which should be to persuade the mass of the people that human society can be a friendly society.

#### **"AS MAY BE REQUIRED BY HIM"**

The local medical committee of the London Executive Council is to be congratulated on drawing attention to the slipshod wording of a paragraph of the model allocation scheme put forward by the Ministry of Health to executive councils for consideration. The ambiguity is explained in a letter printed in the *Supplement* at page 152. As Dr Robinson says, the scheme provides that attendance at the patient's home shall be the duty of the practitioner "as may be required by him"—the patient. Clearly the duty to attend should depend on the patient's needs, not on his demands. No doubt an honest, if stupid, mistake has been made, but if local executive councils do not correct the phrasing in their allocation schemes, as London has already done, medical practitioners may be subjected to many unjustifiable summonses to patients' homes. Some executive councils outside London may have already altered

the wording of their schemes. If there are any that have not done so but have adopted the model scheme verbatim so far as this part of it is concerned, we would urge their medical members to take up the point in the interest not only of the profession but of the patients as well. The need for protecting practitioners from an abuse of their time is clear enough, but it is equally to the advantage of the sick that their medical attendants should be protected from the unnecessary demands of every crank and *malade imaginaire* who insists on the right to a visit in his home whenever he chooses to "require" it. The strain of medical practice is great enough without this added burden.

### WHITE BILE AGAIN

The modern conception that infective hepatitis is a disease of the liver cells is based on apparently incontrovertible pathological evidence. Aspiration biopsies demonstrate the lesion for all to see, and serial examinations show the processes of healing or the progression to either atrophy of the liver or nodular cirrhosis. So complete and so satisfying is this picture that earlier theories are completely discarded. Nothing is heard nowadays about plugs of mucus blocking the biliary passages.

But just as contemporary opinion accepts the demonstrations of central lobular necrosis it should not be forgotten that earlier pathologists were equally satisfied by Virchow's mucus plug. Probably most practitioners can recall demonstrations of this which were convincing enough to them as students, though some may have become less enthusiastic when in their turn they were expected to demonstrate it. It is now realized that such plugs were not the cause of the jaundice but were the result of it, but in accepting this explanation there has perhaps been a tendency to disregard their presence and to forget the possibility that such plugs may sometimes cause symptoms.

Bergenfelt<sup>1</sup> has recently published a paper which re-directs attention to these matters. During an epidemic of infective hepatitis in Sweden he was asked to operate upon a patient who had been jaundiced for seven months and who was suspected of having a biliary obstruction. A nodular cirrhosis was found, and the bile ducts were apparently normal. During the operation cholangiography was performed, the contrast medium being injected directly into the common duct, a normal picture was obtained, there being free passage of the dye into the duodenum. To everyone's surprise this operation was followed by rapid clearing of the jaundice, and at operation for a ventral hernia two years later the liver was found to be macroscopically normal. Subsequently Bergenfelt operated upon six other cases of hepatitis, irrigating the biliary tract with saline as well as performing cholangiography. If none of these cases was as sensational as the first—some had been jaundiced for only two weeks—each was followed by an equally prompt clearing of the jaundice and clinical recovery.

In order to explain these satisfactory results the author revives the conception that the biliary passages become blocked by desquamated cells and mucus. To support this theory he presents some post-mortem evidence and recalls the old method of treatment of prolonged jaundice by means of duodenal lavage with magnesium sulphate. This was a method which had a great popularity in France between the wars and was used by some in this country with occasional dramatic success. Cases of infective hepatitis in which the jaundice persists and deepens and in which considerable damage is done to the liver are distressing problems to the physician. Bergenfelt's work

gives hope that operative treatment may provide a means of affording relief. No less valuable, however, is his demonstration that apparently well-established cirrhosis can occasionally regress and complete recovery occur.

### THYROID ENLARGEMENT AND DRINKING-WATER

The Medical Research Council's War Memoranda provided a useful series of pamphlets summarizing available knowledge for practical purposes and reporting the results of specific investigations. They are sensibly going to be continued in peacetime, and the eighteenth (the first to omit "War" from the series title) has recently been issued.<sup>1</sup> The report is of an investigation of the relation between thyroid enlargement and the iodine and mineral contents of local drinking-water. The findings mainly concern school-children, of whom about 6,000 were examined, but some adults were also studied. The thyroid glands of the subjects were graded by eye as (1) invisible, (2) visible but soft, smooth, and symmetrical, (3) conspicuously enlarged without firmness, asymmetry, or nodular change, and (4) as pathological if enlargement was accompanied by the latter characteristics. This simple method enabled 80–100 children to be classified by two observers in an hour. Two observers are recommended "in order to provide a check in cases of doubt or difficulty." However, no data are given in the report regarding individual variation in grading, so that it is impossible to assess the reliability of the method.

The results broadly confirm the fact that the incidence of thyroid enlargement is inversely related to the iodine content of the drinking-water, but there are many discrepancies in detail. These are probably related to the hardness or softness of the water: where the water is very hard the incidence of enlarged glands is likely to be higher than in another area with water of the same iodine content but which is softer. That these suggestions are correct is borne out by selection from the large amount of data provided in the report, but it is odd in these days to find that not even the simplest statistical analyses have been applied to the figures to assess the significance of the conclusions.

Where a study was made of the state of the thyroid in all the inhabitants of a village in the goitrous region in North Oxfordshire the non-pathological enlargement was very differently distributed from the goitrous enlargement. The former was found in 35 and the latter in 114 of the 575 people examined. Of the enlarged glands 70% were present in the 16–26 age group, while the goitres were much more evenly distributed, most (23%) being in the 36–46 group. This may be taken to support the view that the enlargement is physiological in the sense that it reflects a greater need for thyroxine (and so for iodine) during puberty, and that it may not necessarily lead to goitre later. At the same time there is no doubt that this enlargement is a sign of iodine deficiency and calls for remedial action. Without entering into the question of what part the drinking-water bears in the total iodine intake, the widespread occurrence of thyroid enlargement found among the children warrants the practical recommendation of the investigators that the general use of iodized salt is desirable in Great Britain.

Mr L. E. C. Norbury will deliver the Bradshaw Lecture before the Royal College of Surgeons of England (Lincoln's Inn Fields, London, W.C.) on Thursday, Nov. 11, at 5 p.m. His subject is "Proctology Throughout the Ages."

## SOUTH AFRICAN MEDICAL CONGRESS MEETING AT PRETORIA OVERSHADOWED BY TRANSSVAAL DISPUTE

The 36th South African Congress was held this year at Pretoria. A very successful meeting on its scientific and social side, it took place in the midst of the struggle over the Public Hospitals Ordinance in the Transvaal, which was due to come into operation within a week of the opening of the Congress and which has aroused the almost unanimous opposition of the medical profession in the Province. The annual general meeting of the Federal Council of the Medical Association of South Africa which preceded the Congress was largely occupied with this controversy.

At the official opening of the Congress in the City Hall Dr C G L van Dyk was formally inducted into the presidential chair by Dr A W S Sichel, president of the Federal Council. In his address Dr van Dyk quoted the favourable health statistics of Pretoria, and went on to discuss the question of pain and its manifestations among the different races of South Africa. Field Marshal Smuts addressed the assembly on communal health and nutrition and spoke of the importance of research in this field and the need for financing health measures by the modern State. On behalf of the Royal Society of Medicine in London its emissary, Mr L R Broster, presented the Field Marshal with the roll of honorary fellowship of that Society, together with a specially bound edition of the reports which the Society has published of the Inter-Allied Medical Conferences held under its auspices during the war.

The first plenary session of the Congress was devoted to the subject of malignant disease. Dr F J Murray discussed the question of carcinogens in the production of neoplasms and the physical and biochemical changes found in cells. Professor M Coe Rous outlined a comprehensive scheme for tackling cancer by educating the public, training the general practitioner, co-operation between surgeons and other specialists and better facilities for detection and research. Dr M Weinbren spoke of the types of carcinoma to be treated by surgery and radiotherapy, and suggested that expectations about radioactive isotopes had not been fulfilled. Dr M Suzman reviewed the part played by the endocrines in the production and treatment of cancer.

At another plenary session the subject of discussion was arthritis, and was introduced by Professor G A Elliott, who thought that the advance of medical treatment had been hindered by an uncritical approach. Other speakers dealt with clinical types, the plethora of treatments, and the role of physical medicine in the management of the condition. The economic and social aspect was also considered. Many sectional meetings were held. One combined meeting of certain sections was addressed by Mr Broster on the adrenal cortex and the effect of adrenalectomy on steroid metabolism. Other sectional subjects were bone syphilis in the African native, peptic ulcer, contact dermatitis in certain trades, health education, and social medicine.

### The Hospital Plan in the Transvaal

The Transvaal Administration Ordinance enacts free hospital treatment for all members of the community (including the 30% or so of Europeans, who have hitherto paid their hospital charges and doctors' fees) and the setting up of medical centres. A plebiscite of the profession in the Transvaal showed a majority of well over 90% against the ordinance. The effect of the provision and the grounds of the medical opposition were described in the *Supplement* of Sept 18 (p 123).

The Administrator has refused to consider a means test which is not indeed provided for in the ordinance itself. A motion from the Southern Transvaal Branch, afterwards adopted by the Federal Council with one exception, was that members of the Association should be advised not to enter the Provincial Health Service. While the Congress was proceeding at the end of July an arrangement was agreed to whereby pending a review of the situation by the Transvaal Provincial Council, members of the profession would continue their services in the hospitals after the appointed day (Aug 1) on a voluntary basis.

Unfortunately, in these resumed negotiations, no solution has been found and in an attempt to break the deadlock the Provincial Administration by-passed the Medical Association

and made a personal approach to every doctor on the honorary staffs of provincial hospitals, asking him whether he was willing to carry on and what remuneration he would require. The first of four questions addressed to members of the staff of the Johannesburg General Hospital was as follows:

'Are you prepared to continue in attendance on the patients in hospital under your care as at Sept 30 until they are discharged by you? If so, do you wish to continue such attendance on an honorary basis, or on a basis of receiving payment by the Administration, if the latter, what would you consider reasonable remuneration?'

The Medical Association thereupon advised its members to refuse to negotiate directly with the Administration, and stated that if they complied with the request concerning remuneration they would render themselves liable to disciplinary action on the ground of 'tendering'. The response to the Association's advice is given in the words of Mr H F Prentz chairman of the Hospitals Advisory Committee and one of the advocates of the Administration's scheme: 'With few exceptions, the instructions of the Association have been obeyed. This is a very creditable display of loyalty and solidarity—on the face of it.' But he added that it was reported that what amounted to threats of victimization had been used to prevent members from accepting posts under the new ordinance. These allegations have been indignantly denied. A spokesman of the Federal Council described them as 'despicable'. He said that the doctors were actuated only by a desire to prevent interference with their livelihood, there was no wish to wreck the ordinance, and the medical profession would see to it that medical teaching continued and that the sick poor and emergency cases in hospitals were treated despite the impasse.

The latest advices are that the South African Medical and Dental Council, which controls and directs the profession in the Union under powers given by the Medical Act, is taking up the question directly with the Union Government, considering that the breakdown of clinical medical education constitutes a national emergency because the doctors who refuse to fill the posts offered by the Province would automatically be the teachers under the scheme. Moreover, it would be impossible for the hospitals in the Transvaal to carry on their medical services, because the full-time staffs are inadequate in the big hospitals and non-existent in the smaller.

## BRITISH ASSOCIATION OF PLASTIC SURGEONS CLINICAL CONGRESS

The British Association of Plastic Surgeons, which was formed in November, 1946, held its Summer Congress on Sept 16, 17, and 18 at Oxford and Stoke Mandeville under the presidency of Professor T P Kilner. The meeting was attended by 90 delegates including members and visitors from America, Belgium, Denmark, Ireland, Norway, Sweden, and South America.

Dr Sumner L Koch (Chicago), the guest of honour, addressed the Association on the surgery of the hand. He had found that healing had been more certain since the application of antiseptics had been abandoned. Ordinary soft white soap was used to prepare the operative field the afternoon before the operation and again, by an assistant, on the operating table. He used an inflatable arm cuff, and was prepared to leave this on for as long as three and a half hours as a tourniquet during the operation. No sign of paralysis has yet been seen using this technique. The cuff was deflated at the end of the operation to allow the ligation of any large vessels and was then reinflated until the final bandage had been applied.

Dr Koch said he would not suture tendons divided within the digital sheath, since the blood supply was so poor, but preferred to use a tendon from the dorsum of the foot as a graft passing this around the base of the distal phalanx. All suturing was carried out with fine silk in preference to any form of wire. He had had no personal experience of wire, but had not been impressed with the results where it had been employed. Tendon grafts to fingers were never undertaken until all the joints were mobile. For uniting divided nerves he advised the finest cataract silk on eyeless needles in the form

of simple interrupted sutures. The hand and fingers were splinted in full flexion for three weeks, and this was followed by splinting to prevent full extension. The results of nerve suture were very poor if it was carried out more than two years after injury. Finally Dr Koch demonstrated a simple ball and gutter type splint which was used to maintain the hand in the position of function and could be applied to either hand.

The second day of the Congress was spent at Stoke Mandeville where papers were presented during the morning by members of the Plastic Surgery Unit. Mr R J V Battle, discussing the treatment of decubitus ulcers in paraplegic patients, emphasized that free grafts were of no value. Carefully planned local flaps were the solution to this problem, but operations should not be undertaken unless the patient was in good condition, for, at best, healing tended to be delayed.

Mr R P Osborne, discussing facial paralysis, said that these cases should be sent to the plastic surgeon very much earlier than was the custom. Many of the poor results following recovery of nerve function, or after a nerve-grafting procedure, were due to stretching of the paralysed muscles in the intervening period.

Professor T P Kilner projected a number of slides illustrating the commoner secondary cleft-lip and palate deformities and the results of their treatment. Other papers were on haemangiomas by Mr J P Reidy, oro-antral fistulae, by Mr E W Peet, mandibular asymmetry, by Mr D Greer Walker, and the use of prefabricated cartilage inlays for pinna support, by Mr H E Blake. During the afternoon a ward was set aside for the demonstration and discussion of selected cases. The lecture hall was transformed into a projection-room for a continuous show of films from the Stoke Mandeville Plastic Unit library and the dental department arranged a demonstration of the extensive work they have done in association with the Plastic Unit. Dinner was held in the Hall of St John's College, and the evening concluded with interesting and informal talks by W C Costin and H W Thompson.

The morning of the last day was occupied by the presentation of papers by visitors from America. Dr Gustave Aufricht (New York) on mammoplasty. Dr Milton Adams (Memphis) on an operation for bilateral hypertrophy of the masseter muscle. and Dr Neal Owens (New Orleans) on osteoporosis following burns. During the discussion on mammoplasty both Professor Kilner and Sir Harold Gillies emphasized that reliance should not be placed entirely on the skin to provide the shape of the breast.

### MEDICAL MICROFILM UNIT

The microfilm unit of the Royal Society of Medicine has been installed in reconstructed (formerly bomb damaged) premises in Dering Yard New Bond Street close to the Society's headquarters, and was formally opened on Oct 18. Hitherto the unit has worked in cramped quarters at the Society's house, but now it occupies three floors of one building and has printing, developing and drying facilities so that it is possible to turn out 25 000 pages of microfilm a day. The unit was opened by the Chief of the Scientific Mission at the U.S. Embassy, Dr Earl A Evans who at the last moment took the place of the American Ambassador and representatives were present from the Foreign Office, the Ministry of Health, the Ministry of Works, the Medical Research Council, the British Council, Unesco and the Centre National de la Recherche Scientifique of Paris.

Sir Henry Dale, President of the Royal Society of Medicine, in calling upon Dr Evans to unveil a tablet commemorating the occasion, stated that the creation of this unit for the production and distribution of microfilm copies of medical publications covering many countries had been made possible by the munificence of the Rockefeller Foundation. For many years the Royal Society of Medicine had been developing the service of its medical library not only by lending its books to its members but by preparing bibliographies for them and making photostat copies of articles or extracts on request. Such a service became increasingly difficult to maintain when war broke out and the medical men who needed these facilities were scattered all over the world but the invention of the microfilm made it possible to continue the supply of material,

a camera in the Society's house being used for the purpose and the films, with the necessary projectors for reading them being conveyed to their destinations from the Rhine to the Jumna by the R.A.F. As the war progressed, however, it was realized that there was here an opportunity for a larger service owing to the appalling devastation of libraries whereby much of Europe and even of Asia was becoming largely bereft of these sources of medical and scientific knowledge.

Much encouragement was given by the Minister of Health who helped the Society to secure the necessary licences for rebuilding and equipping the premises and ensured the good will of his colleagues in the Foreign Office and Board of Trade. Sir Henry Dale said that if Mr Bevan was not already surfeited with expressions of gratitude from medical quarters they would like to convey to him an expression of their thanks for the support he had given to this enterprise. A well-equipped unit was now available with an efficient staff. The first objective was to restore the war-damaged libraries of Europe and beyond by means of microfilm copies of medical journals which they had lost and which were out of print or otherwise irreplaceable. The majority of medical libraries, to the total number of 173, were associated with the scheme, which ranged from Reykjavik to Singapore, and 3,500 volumes otherwise unobtainable had already been supplied, and there were orders for at least 10,000 more.

Dr Earl Evans, in performing the opening ceremony, spoke of America and Great Britain as sharing a common medical tradition, and said with what gratification the United States in the shape of the Rockefeller Foundation, found itself associated with this project. Scientific progress was only possible where research was unhampered, as it was in their respective countries, and where free interchange took place.

### MEDICAL FILMS

In connexion with the second International Congress of the Scientific Film Association, recently held in London, a 'Film Festival' was arranged during which the applications of the film to education, medicine, and industry were demonstrated. Some two dozen films were shown, varying in length from three to thirty minutes. Most of the films were intended for medical education and research, but a few were designed for health propaganda to the cinema-going public. Some of the films had been produced in medical schools. One of them, summarizing the first clinical lecture to medical students on the subject of acute inflammation, was the work of the department of medical photography at Westminster Hospital Medical School, and another, illustrating a case of chorea, the work of the department of child health at Guy's Hospital. Others were the production of individual workers—for example Mr Gwynne Evans's ingenious 20 minute reel showing the behaviour of the oro-facial musculature during breathing and swallowing, Dr Bryan Stanford's short films on how to evert the upper eyelid and how to apply the Aschheim-Zondek test for pregnancy, and Dr David Morris's excellent clinical case record of hereditary ataxia. Other films came from the great commercial film houses or the laboratories of food and drug manufacturers and yet others from American and Continental universities, the State Film Centre at Copenhagen and the National Film Board of Canada.

This heterogeneous collection was unequal in value, and the more elaborate films were not necessarily the best. For example one film from Denmark which showed the systematic examination of a patient for signs of syphilis while it indicated the technique for examining skin, mucous membranes, and lymph glands was criticized on the ground that it gave no indication of the lesions which were discovered. A film from New York University which was described as an integrated study of the interaction of the child with his environment showed the behaviour of small children and their parents at a psychiatric interview but no allowance appeared to have been made for the probability that the presence of the camera had a disturbing effect on the parents in handling the children, even if the children themselves were too young to be influenced by its presence. On the other hand some of the short films were admirable for teaching nurses and clinical records as for example the work of the Wellcome Film Unit in illustrating

cases of rheumatic chorea and myasthenia gravis, or of the Research Unit at Columbia University illustrating the toxic effects of streptomycin, particularly on the eighth nerve

The medical film is no longer a novelty and those attending the demonstrations were reminded of what has been achieved in the course of a quarter of a century. In connexion with the recent centenary of the American Medical Association a film was prepared showing the evolution of the medical film itself. A copy was kindly sent to the British Medical Association which allowed a private preview on this occasion. "The Medical Film" is a 16 mm reel running for 25 minutes. It is in colour and is accompanied by a sound commentary. It reviews the development of the medical film since the early 'twenties—the introduction of the animated cartoon, the combination of the film with radiography and with photomicrography, and the progress in colour. It is put together with the usual American talent for production. A sight of the early films of operations made one wonder how anyone could have learned anything from those confused moving masses of black and white. A British film of the operation of subtotal hysterectomy for multiple fibromyomata followed. It was recorded for post-graduate teaching and exemplified the high level of cinematic technique now attained.

Subcommittees have been set up to study the following problems: (1) The establishment of an international data card for compiling a master index of scientific films available throughout the world and the formulation of methods of appraisal of these films. (2) The joint production by a number of countries of films of common interest. (3) The exchange and distribution on the widest scale of scientific films and the customs regulations affecting such exchange. (4) The setting up of a scientific-film reference library. (5) The exchange of information between nations by means of a regular journal."

### SCOTTISH SOCIETY OF THE HISTORY OF MEDICINE

The third meeting of the Society was held in the Hall of the Royal Faculty of Physicians and Surgeons, Glasgow, on Oct 20 with Dr Douglas Guthrie in the chair. Professor J D Mackie of the chair of Scottish history and literature, University of Glasgow, described how the early history of Glasgow was dominated by that of the bishopric of the city. The University founded in 1451, was at first modelled on French lines, but after the Reformation it was reorganized by Andrew Melville, and since then it had taken its place as one of the great seats of learning in the world.

Mr A L Goodall, honorary librarian, said that the Faculty was unique among medical corporations in this country in that both physicians and surgeons were united in one body. The Faculty founded in 1599 by Maister Peter Lowe, received its charter from James VI the same year. Among its many duties were the examination and licensing of all surgeons in the West of Scotland, supervision of their conduct, and ensurance that any drugs supplied were of the highest quality. A service of free medical aid to the poor of the city was a noteworthy feature of the Faculty's activities. Many famous men in medicine and surgery like Cullen, Lister, and Macewen had associations with the Faculty which will celebrate next year its 350th anniversary.

The Ministry of Health states that full time nursing and midwifery staffs in hospitals in England and Wales now part of the National Health Service have risen by 2 000 within 12 months. In June last the total including those trained and in training, was 117 741 compared with 115 529 a year earlier. Part-time nursing and midwifery hospital staffs over the same period rose by nearly 7 000—from 10 700 to 17 380. On the domestic side full time staff went up from about 96 500 in June, 1947, to 99,700 in June, 1948, and part-time from 18 000 to 21,575. This general increase in hospital staffing has not only made it possible to shorten the nurses' hours in many hospitals and to institute a 96-hour fortnight but to reopen beds closed through lack of staff. In mid-1947 there were about 63 000 beds out of action for this reason but by June this year nearly 6 000 of them were again available for patients. Every addition to the hospital nursing and midwifery staffs now means either the opening of more beds or the improvement of working hours and conditions and sometimes both.

## Correspondence

### Neonatal Asphyxia

SIR,—While all must admire the way in which Dr F C Eve (Sept 18, p 554) insists on the mechanics of resuscitation, it does seem sad that he and nearly everyone else should ignore the brilliant researches of the late Sir Joseph Barcroft into the physiology of neonatal respiration. He showed quite conclusively how minute was the amount of oxygen in the foetal circulation at birth and how the agent in starting respiration is not oxygen lack or carbon-dioxide stimulation but sensory stimuli either from the skin or from muscles or other organs. The foetus that does not breathe may be suffering from a type of shock but it is fundamentally a different type from surgical shock. What it awaits is some stimulus which will penetrate to the brain and cause the reflex respiratory efforts which nature has provided for.

I have drawn attention in previous letters to the way in which Barcroft's researches entirely explain the dramatic way in which an injection of "cardiazol"-ephedrine starts an asphyxiated foetus into full respiration in a matter of seconds, but this fact is consistently ignored in all the textbooks of midwifery that I was able to see at the B M A exhibition at Cambridge this year. The latest one a pre-publication copy I saw last week in London, even speaks of 'sadistic attacks' on asphyxiated babies as if Freudian jargon could replace or displace exact scientific knowledge. If the author had listened to the late Sir Joseph he would have learned that the nose of the foetal sheep is the area which first shows any response to stimulation and it is on this area that the lamb normally falls when it is dropped thus providing the maximum stimulus on the most sensitive area in order to ensure the immediate commencement of respiration. One might think that the spirit that refused to listen to Semmelweis still stalks in our maternity wards for asphyxia which directly or indirectly causes 75% of neonatal deaths as well as many more still-births is still treated as if one of our greatest experimental physiologists had never shown a better way. And not only do babies die but homes are plunged in grief (as I know for my first child was still-born) because doctors will not apply the very simple and effective remedies that science has provided to make use of the knowledge that has been gained.

Dr Eve rightly touches on the question of the final result of these long-asphyxiated babes. The first baby I saw that was so long asphyxiated that I ventured to give it cardiazol-ephedrine intracardially now nearly 9 years old has never needed any medical attention and is very bright mentally, and all the others are normal. I quoted my last case recently in the *Practitioner* and though one swallow does not make a summer this one case does mean that we must radically alter some of our conceptions of neonatal asphyxia. It was a child born with a fairly easy forceps delivery that breathed promptly and well. In 15 minutes or so the breathing began to get weaker and gradually ceased entirely the child becoming blue and finally white. Before he reached this stage I had given him first 0.5 ml of cardiazol-ephedrine intramuscularly and then a second dose, without any appreciable effect. When he seemed quite dead I gave him yet a third dose into the left ventricle and this to my amazement was followed by an almost instantaneous resumption of respiration and crying. I was no less surprised when the babe was living next day and now he is a bonny babe of 7½ months, already beginning to say "Baba, Dada," etc.

I think that practically every doctor would have said without hesitation that this was a case of fatal intracranial injury yet it was apparently merely a case in which for some reason the brain did not sufficiently well change over from its initial response to sensory stimuli to regulation by oxygen and CO<sub>2</sub> in the blood. If this is true it is of the utmost importance that we should recognize that such a failure can occur for looking back I can now recall several cases in which this may well have been the cause of neonatal death and the case I have quoted suggests that appropriate treatment might have

prevented it. There is little doubt that such treatment would also avoid the later complications of feeble initial respiration—i.e., pneumonia, etc.

I may perhaps also recall a case I reported in 1940 a boy drowned from long immersion who recovered rapidly after treatment based on the assumption that this basic pattern of respiratory response to cutaneous stimuli persists, as at birth, after the response to carbon dioxide has been lost through poisoning of the respiratory centre. The bearing of this supposition on the treatment of anæsthetic as well as drowning casualties is obvious. These are all problems of applied physiology, and I suggest that it is not to the credit of British medicine that in this country, where the key was found, they have been so long and so disastrously ignored by those whose work the discovery would most benefit—I am, etc.,

Winsford Cheshire

### Ruptured Uterus

SIR—I am in agreement with Mr C Scott Russell (Oct 16 p 722) in his condemnation of classical caesarean section. It is an operation practised all too commonly in this country. I would go further and suggest that in abdominal hysterotomy with or without sterilization, it is possible to perform a lower-segment operation but in miniature. The uterus can be incised transversely above the internal os and the peritoneum of the utero-vesical pouch used to cover the incision.

Recently I saw a case of rupture of the uterus at term which followed an abdominal hysterotomy for placenta prævia at the 24th week of a first pregnancy. The rupture of the uterus extended from fundus to cervix as in Mr Keith Vartan's case (Sept 25, p 602). It was possible to conserve the uterus, and the woman has since menstruated normally. The transverse fundal incision for abdominal hysterotomy carries with it not only the danger of rupture but also intestinal obstruction—I am, etc.,

London WC1

W C. W NIXON

### Classical Caesarean Section

SIR—Mr C Scott Russell (Oct 16, p 722) surely uses rather harsh words when he condemns as an "abomination" an operation (classical caesarean section) which has saved countless foetal and maternal lives. Though the classical caesarean section is admittedly not an edifying spectacle and has certain disadvantages including occasional rupture of the scar subsequently, one can recall so many classical operations in the past that have had a happy outcome both at the time and in subsequent pregnancies. Lest one be carried away by a youthful enthusiasm for the lower segment operation to the exclusion of any other it might be well to remember that there are still certain cases in which the classical operation is probably safer.

The type of case I have in mind is that in which on opening the abdomen one sees an enormously rich venous plexus overlying the lower segment, sometimes associated with placenta prævia. I have often in such cases retracted or enlarged the abdominal incision upwards and performed the 'abominable' operation with a sigh of relief. It is better, I think, provided it is a 'clean' case to accept the relatively slight and more remote risk of subsequent rupture of the scar than the immediate one of severe bleeding. Surely this is an example of where one must adapt the operation to the patient, not the patient to the operation—I am, etc.,

Exeter

P M G RUSSELL

SIR—Mr Keith Vartan's medical memorandum on 'Ruptured Uterus' (Sept 25, p 602) has reopened the caesarean controversy, and I am interested to see the fervour with which Mr C Scott Russell (Oct 16, p 722) condemns the classical operation. He follows the fashion of the moment which condemns the older operation out of hand. Other operations have suffered the same unthinking treatment and have subsequently been received back into favour by a later generation which has found out advantages which their fathers were too blind to see.

The lower segment operation has such obvious advantages in most circumstances for reasons which are too well known to repeat here that it is rightly used in the great majority of cases. But there will always remain a small number of young

women in whom an elective section is necessary and in whom there is good reason to expect a normal delivery in a future pregnancy. It is very necessary that the form of operation performed in such patients should not prejudice this possibility, and I have the idea, backed by a reasonable amount of personal experience, that the transverse scar of the lower segment operation interferes by its interruption of the neuromuscular pathways both with the proper relaxation of the cervix and with the reflex from pressure on the latter which helps to maintain the pains of labour. I have often been disappointed in the progress of labour in women who have had a previous lower segment operation, even to the point of having to perform a further section for no other reason than mere lack of progress after many hours of poor pains in the absence of any other complicating factor. On the other hand, it is the usual experience that in similar circumstances the woman who has a classical scar has a quick and easy labour. Some will counter this by saying that the incision in the lower segment should be longitudinal, but if a woman is only in the early stages or not in labour at all an up-and-down incision becomes a lowly placed classical one—and this is the right position for a classical scar anyhow.

I seldom perform the classical operation myself but I am sure that this complete condemnation of it is illogical. From the physiological aspect the transverse incision is wrong, but we accept it in most cases because there are other more important reasons for doing so. But there is no reason to persist when none of these reasons is present and there is a strong desire to preserve a fully physiological organ. I do not believe that a lowly placed classical scar—that is, one which follows an incision which is started as low as possible in what there may be of a lower segment at the time and is continued upwards only as far as may be necessary—is more likely to rupture than one wholly in the lower segment in whatever direction it may run.

Until more is known about it I shall continue to avoid cutting across the uterus for this reason and shall be content to make my incision in the up-and-down direction in the few suitable cases, even if this means that I must occasionally trespass into the forbidden upper segment. My lower segment operating record will be sullied but I shall have, I believe, done the lesser evil and perhaps I shall be doing fewer repeat performances—I am, etc.,

Swindon

GUY ROWORTH

### Post-gastrectomy Syndrome

SIR,—In the annotation on the post gastrectomy syndrome (Sept 11, p 524) the following statement is made: "This conception is of particular interest in view of the similar syndrome which is known to follow vagotomy for duodenal ulcer, and careful observation of these cases is indicated."

I feel that this statement may arise from a misunderstanding for I have not observed a single example of such a syndrome during the follow up of seventy cases of vagal section, nor have I seen a single reference in the literature to it (as an abstracter I have access to most of the literature on the subject). Reference to the text of the article by Dr W T Irvine (Sept 11, p 514) on which your annotation was based lends support to this view, for your meaning could be read into one sentence taken out of context: "Moore *et al* (1947) also observed such post prandial symptoms following vagotomy."

In its context the meaning of that sentence is that most gastric sensations as for example a feeling of distension, could still be appreciated after vagotomy. The observation was made to support the thesis that sensation is not carried in the vagal nerves. In Moore's article the relevant passage is: "Nausea, vomiting and epigastric sensations of fullness may still be experienced." But this does not indicate that they are experienced as a syndrome, as can be seen from the sense of the rest of that sentence: "and there is no change in the sensory threshold to balloon distension of the oesophagus, stomach, duodenum, jejunum, and ileum."

I would be grateful if you would clarify the point by publishing the reference to the work in which the report of a 'post gastrectomy-like' syndrome in vagotomy cases is made. If it is a fact that it has occurred then as you state it is important enough to warrant careful observation of

acetarsol vaginal compound

The high incidence of pathogenic protozoal infection in leucorrhœa justifies the use of 'S V C' in most cases of this condition met with in general practice.

'S V C' contains acetarsol combined with a suitable carbohydrate for promoting the growth of Doderlein's bacillus

The product is available in effervescent tablets for insertion and in powder for insufflation

## NEW TREATMENT FOR ASTHMA

Relatively free from the undesirable cardiovascular and other side-effects of adrenaline injections, 'Neo-Epinine', a recently-developed homologue of adrenaline, possesses marked advantages in the treatment of bronchial asthma. It may be given sublingually or by oral spray. The drug has been found to be an effective substitute for adrenaline. Superior to ephedrine, it does not cause sleeplessness.

### 'NEO-EPININE'

ISOPROPYL<sup>NAME</sup>ADRENALINE SULPHATE

Tablet brand compressed products for sublingual administration each containing 20 mgm. in bottles of 25 and 100. Spray Solution containing 1 per cent of drug in bottles of 10 cc. Literature and samples on request.

BURROUGHS WELLCOME & CO (The Wellcome Foundation Ltd) LONDON

## THE IMPORTANCE OF SELECTION

As in most things the best results depend on the correct selection of implements so success in the field of haematology depends on the correct choice of a haematonic. Folic acid and iron are haematonic fundamentals in that the former is the maturation factor for red cells (or its precursor) and ferrous iron is the principal building stone of haemoglobin. 'FOLVRON' supplies both these essential factors in a readily absorbable form.

vagotomy cases, for in those cases the autonomic balance has been upset in favour of the sympathetic. Unfortunately no good evidence has been provided in the post-gastrectomy cases that adrenaline secretion can be blamed for the symptoms, it would have been of some assistance if blood pressure recordings had been made.

Finally, it would be interesting to know what proportion of Dr Irvine's series of gastrectomies these 24 cases provide—I am, etc,

Birmingham

### Diabetic Coma

SIR,—Professor E P Joslin (Oct 2, p 657) makes a request for constructive criticism. Impressed by his series of 62 consecutive patients with diabetic coma without a death, at the beginning of 1944 we issued to medical staff, ward sisters, and students at the Radcliffe Infirmary a summary of the treatment suggested in the paper by Joslin, Root, White, and Marble in the *Journal of the American Medical Association* (1942, 119, 1160). The death rate from diabetic coma since this change has been reduced to about a third of its previous level.

My first patient treated on the Joslin regime was a young woman in deep coma with previously undiagnosed and untreated diabetes. She made what we thought was a good recovery. On the following day she asked the nurse for a drink and on being sat up to receive it fell back dead. The post mortem examination revealed no gross organic disease. We therefore added to our summary of treatment a paragraph as follows:

"Aftercare. It is important to realize that a patient who has come round from diabetic coma has recently been in a condition of profound circulatory failure and is still ill. The patient should not be allowed to sit up in bed, and should be nursed as a cardiac case for at least a week."—I am, etc,

Oxford

ALEXANDER COOKE

### The Walking-calliper

SIR,—Dr H L Rogerson (Oct 16 p 724) writes that he does not know of an organization concerned with research in this particular instrument (the calliper). In 1945 the British Orthopaedic Association appointed a Surgical Appliances Subcommittee to investigate the design, materials, and manufacture of surgical appliances and the calliper in particular. The personnel of this Committee includes an anatomist, a physiologist, an engineer, the director of a large appliance factory attached to an orthopaedic hospital, as well as orthopaedic surgeons. The Nuffield Provincial Hospitals Trust has generously supported the research so that it was possible to appoint an engineer as a Research Fellow.

The problem of the calliper has taken precedence in the investigations which are not yet completed. The important matter of standardization of small parts and screws, so that repairs can be carried out without delay is one item of policy stressed by the committee.—I am, etc,

ST J D BUXTON

Subcommittee B O A

London WC2

### Bronchial Carcinoma

SIR,—Mr R C Brock in his paper on bronchial carcinoma (Oct 23 p 737) remarks that though there remains much room for improvement in the surgeon's technique in dealing with this condition the greater responsibility rests with those who have the task of making the diagnosis or thinking of the diagnosis. With this dictum I am in general agreement, but I would suggest that there is at present an even more disheartening obstacle to the efficient application of surgical measures than diagnostic delay. This is the difficulty and delay experienced in the admission of patients to hospital.

Even when the diagnosis has been established and the case is regarded by the surgeon as suitable for an attempt at radical treatment it is often a matter of the greatest difficulty to find a bed in a thoracic surgical centre.

I do not wish to discuss controversial aspects of this problem such as the present deplorable necessity to assess priorities to be given to various categories of patients—for instance, to young patients with relatively curable conditions such as unilobar bronchiectasis or pulmonary tuberculosis requiring surgical treatment relatively to older patients with malignant disease whose prognosis even with surgical treatment is on the whole unfavourable. My object is to stress that, as long as there is delay in securing admission of a patient with possibly operable bronchial carcinoma to a suitable centre for surgical treatment responsibility for failure to make generally available the benefits of advances in surgical technique rests with those responsible for the organization and administration of our hospital services even more than with the clinicians responsible for making the diagnosis.—I am, etc,

### Reactions to Intravenous Sclerotics

SIR,—Though most would agree with Dr R E Sidebotham (Oct 2, p 661) that sodium morrhuate is an obsolete drug—the Council of Pharmacy and Chemistry of the A M A in 1942 recommended the withdrawal of the 10% solution—I think it would be unfortunate if the impression were produced that monoethanolamine oleate is entirely free from risk.

In the course of the past year, during which I gave about 1,000 injections of 'ethamolin', two serious reactions were encountered. A severe urticaria developed ten days after one injection but the other case was more alarming. Like Dr C E Taylor's case (Sept 18 p 573), the patient had left the hospital, when she became faint. She was brought back by a passer-by and, when I saw her some twenty minutes after the injection, appeared moribund. Rapid deterioration was followed by a slight convulsion and apparent death. Fifteen minims (0.9 ml) of 1 in 1,000 adrenaline was given intramuscularly, and almost simultaneously the colour improved and she began to breathe. Consciousness gradually returned, but about ten minutes later severe asthma developed. This responded to 7 minims (0.42 ml) of adrenaline but was followed by two further attacks at ten-minute intervals also responding to 7 minims of adrenaline.

The patient remains well since, she has never had any other attacks of asthma or evidence of allergy. The injection which produced the attack was the sixth given into residual varicosities after a ligation and injection operation. The previous injections had produced no unusual effects. As a result of this alarming experience I would stress that whatever agent be used patients should be asked to wait a short while after their injection, and, of course, adrenaline should always be available.—I am, etc,

### Maxillary and Mandibular Neuralgia

SIR—In his reference to Costen's syndrome as a cause of facial neuralgia Dr J H Young (Oct 2, p 660) mentions pain which may be unilateral or bilateral, local, or referred to jaws, eye, ear, or mastoid, but he does not mention the grating, clicking and locking of the joint with the restriction of movement which are very common features of traumatic temporomandibular arthritis. If the condition is unilateral there will be a swing of the jaw to the affected side on opening the mouth. A burning sensation in the tongue, glossodynia, and even tinnitus and deafness are also described as part of the syndrome though they are not so common as the pain, grating, and limitation of movement which are usually the prominent features in traumatic arthritis.

I am writing particularly however, to point out that this condition is in my experience not confined to edentulous patients but is even more common in patients who have still got many of their natural teeth but who suffer from "close bite" either acquired through extraction of the back teeth or appearing as a result of developmental irregularity in the arrangement of the teeth. These patients have in the first case lost their molar support and in any case have no free

lateral movement of the mandible owing to the interlocking bite. Both of these conditions throw an extra strain on the articulation, setting up the arthritis, which the patient often aggravates by constantly fidgeting and moving the joint when it should be at rest.

It is rare to see any radiographic change in the joint, and such patients may be much relieved by wearing a shield affair over the biting surface of the upper teeth and palate which opens the bite and gives freedom to lateral excursions of the mandible. They may, however, be unwilling to give up wearing the shield even when cured, and if they are pressed to do so may get a recurrence of the neuralgia—I am, etc.,

### A Sign of Pregnancy

SIR,—I have recently encountered for the third time in the past five years a clinical sign which I have failed to find described in the text books of obstetrics. This is a modification of the well known Hegar's sign of pregnancy—namely, softening and compressibility of the lower uterine segment which is characteristically present about the 8th to the 10th week.

This same softening and compressibility of the lower segment is probably responsible for an undue lateral mobility of the body of the uterus, so that on bimanual examination one finds a swelling apparently located in one or other uterine appendage which as in the commoner Hegar's sign, appears to be quite separate from the cervix. The body of the uterus cannot of course be felt separate from this swelling, but it may well give rise to confusion and suggest the possibility either of an ovarian cyst associated with pregnancy, as in a case referred to me last week, or possibly of a tubal pregnancy, especially in a nervous primigravida whose abdominal musculature is poorly relaxed on examination. Under anaesthesia examination will reveal the true state of affairs, and by gentle manipulation the swelling can be made to occupy the corresponding position in the opposite side of the pelvis, but it should often be possible to recognize the condition even without anaesthesia.

I am prompted to write this letter for the purpose of placing this sign on record since I feel that it is of some importance. I have been unable to find it described in any of the textbooks available to me, and I should be glad to know whether it has in fact been previously described and also whether other obstetricians have observed it with any frequency—I am, etc.,

### Shipping the Sick

SIR,—As a ship surgeon of over twenty years' experience I was very sorry and distressed to read Dr B M Newey's letter (Sept 18, p 574). Shipping companies and their agents in the East must be very different from what they are elsewhere in the world. During the above long experience I have looked after the seriously sick, the insane, the suicidal, and even the criminal on board ship, and I cannot recollect ever refusing a case. I have even accepted the urgently ill from other ships on the high seas.

Indeed, I would say to Dr Newey, *Andi alteram partem*. About a year ago from the R N Hospital of a British dependency which shall be nameless I received a brief note that a case of carbuncles and cirrhosis of the liver was coming on board. I was not given a chance of even seeing, let alone declining the case. This was in the afternoon. The patient with his wife arrived at the ship's side at 9 pm within a few hours of sailing having sold up hearth and home. I could not have refused him even had he been on the point of death. Examination in the surgery showed five large active carbuncles, two of them over four inches in diameter. He showed the typical signs of hepatic cirrhosis: hard enlarged liver, jaundice, oedema, sallow complexion. His wife who was present was quite shocked. It appeared that she had insisted on taking him out of hospital, but she stated that had his condition been revealed to her (which apparently it had not been) she would not have done so. I am inclined to think that his removal from hospital was not unacceptable to those in charge.

Fortunately I had an ample supply of penicillin on board and under large doses of this the carbuncles healed in a remarkable way. A few days later, however, his cirrhosis advanced, jaundice deepened, oedema increased, and he died within a few days of reaching the U.K.

Experiences of this kind (fortunately very rare) do not promote "friendliness, delight at receiving case notes, and willingness to accept responsibility—I am, etc.,

Bridge of Weir Renfrewshire

JOHN S MEIGHAN

## POINTS FROM LETTERS

### Shortage of Nurses

Mr W S BRINDLE (Hyde, Cheshire) writes: Mr L H Hornsby, director of public relations to the Ministry of Labour and National Service, writes (Sept 25, p 622), "In his letter Dr N Strang states that the numbers of nurses in employment in this country are dwindling. Nothing could be further from the truth. Could it not? What about, 'The numbers of nurses in employment in this country have dwindled to none'? Presumably Mr Hornsby meant, 'This is wrong.' This saves four words and twenty-two letters. Perhaps *Plain Words* by Sir Ernest Gowers, has not yet found its way to the Ministry of Labour and National Service."

### Traumatic Amputation

Dr G O M DICKENSON (Haslemere, Surrey) writes: When a "dresser" at the Royal Infirmary, Newcastle upon Tyne, in 1897 or 1898 I remember a man being admitted with evulsion of one arm at the shoulder. The traumatic amputation was completed by snipping through a strip of skin about an inch wide. There was very little bleeding. I expect the wound was dressed with perchloride or cyanide gauze, and to the resulting granulating surface skin grafts were applied—each dresser supplying a piece from his own arm. The patient, a burly Irishman, did not take amiss the remarks that he now possessed a bit of good English skin. His recovery was complete and uneventful.

### Oil Baths in India

Dr T N S RAGHAVACHARI (Madras, India) writes: May I supplement the observations of Dr Percy E Turner (April 17, p 758)? There is a popular old-vernacular proverb current in this land which says, "Instead of paying heavy fees to the doctor, pay a small sum regularly to the oil monger and keep fit." The idea underlying this is that systematic oil baths twice a week keep one free not only from skin affections but also from several ills to which flesh is heir. The oil intended for the anointing is often heated well in an iron pan, with the addition of bits of turmeric (the dried rhizome of which is bright yellow in colour and reputed to be rich in carotene and to possess healing properties), a few grains of black pepper, and half a spoonful of cumin seeds. Oil baths have been a great institution in South India and in Bengal too. Expert masseurs are employed by the rich to give them a real good massage with the oil, which is liberally anointed over their bodies. In Travancore, Cochin, and Malabar dailyunctions with simple coconut oil in the case of normal individuals and variously medicated oils in the case of persons suffering from different ailments (particularly those involving the joints and muscles) have for long been and continue to be the most sought after and popular methods in regular use for keeping fit and for restoring tone to the entire system. Sir Robert McCarrison in his wonderful little popular treatise on food speaks very highly of oil baths taken in diffuse sunlight at regular short intervals, as these help considerably to provide vitamin D to the system most naturally and efficiently. An ancient custom of the Hindus is to keep gingelly and coconut oils in big mud pots immediately after the oils are expressed in a wooden mill and leave them exposed to direct sunlight in the open courtyard for a full day or two before storing them in their tinders.

### Vitamin K and Chlbutalins

Dr DAVID P WHEATLEY (Twickenham) writes: Further to my communication on this subject printed in the *Journal* of Nov 1, 1947 (p 689), I append some further experiences in this treatment which may be of interest to anyone wishing to try the method. Using a water soluble preparation (2 methyl-1,4 naphthohydroquinone disuccinate) I have not encountered any pain on intramuscular injection. However, I have found oral administration of 20 mg t.i.d. so effective that I no longer use the intramuscular route. There is a time lag of 4-5 days before any effect is noticeable, and it is only occasionally that the dose can be reduced below this level. Children should not be allowed to suck or chew the tablets as otherwise a moderate glossitis develops which, however, rapidly clears on cessation of the practice.

## Obituary

C M WENYON, CMG, CBE, FRS

By the death of Charles Morley Wenyon on Sunday, Oct 24, British medicine loses one of its foremost protozoologists and one of its most interesting characters. He was the eldest son of Charles Wenyon, M.D., a pioneer medical missionary in Southern China, and was born in Liverpool in 1878. Much of his early childhood was passed in China, in Fatsan, and in moments of stress he was apt to express his thoughts in what he said was Chinese. Wenyon came back to England in 1892 to Kingswood School, Bath, and began his professional studies at Leeds University, later transferring to University College and Guy's Hospital. He obtained a B.Sc. in 1901, and graduated M.B., Ch.B. in 1904. Almost at once he took up the subject of medical protozoology, and in 1905 was appointed protozoologist to the London School of Tropical Medicine, where, in the old Dock Hospital, Sir Patrick Manson was then at the height of his fame. In the following two years Wenyon visited the Sudan, studying trypanosomiasis and malaria; this was his first contact with Sir Andrew Balfour, with whom he was later intimately associated for so many years. Later he wandered over the Middle East from Bagdad to Malta, studying leishmaniasis, which remained for many years one of his major interests.

He returned to the London School of Tropical Medicine, and in 1914 joined the Wellcome Bureau of Scientific Research which had just been founded by Dr—later Sir Henry—Wellcome, with Dr Andrew Balfour as its first director. Within a few months of its foundation both Balfour and Wenyon were seconded for military service. Before the outbreak of war in 1914 the current teaching had been that almost all the dysentery in the Middle East was due to *Entamoeba histolytica* and very little to bacillary dysentery. As a result, in the Gallipoli theatre patients suffering from dysentery were being treated with large doses of emetine and the death rate was in consequence high. Wenyon's investigations in Egypt clearly demonstrated that the greater proportion of cases of dysentery were not due to amoebae, emetine thus ceased to be given as a routine to every patient and countless lives were saved. Wenyon summarized the results he had obtained in the Near East, which is now referred to as the Middle East, in a valuable work written in 1917 in collaboration with F. W. O'Connor, *Human Intestinal Protozoa in the Near East*. In addition he was responsible for the protozoological sections in the first edition of *Memoranda on Medical Diseases in Tropical and Subtropical Areas*, a compilation published by command of the Army Council which has been of inestimable benefit to medical officers in two world wars.

His next task was to investigate the malaria which was completely immobilizing the Allied Forces in Salonika. With the tools at hand it was obviously impossible to deal with malaria in the ways in which it was later overcome in the second world war, but Wenyon's reports had two important results: they served to discourage any further bellicose adventures by the British in the Balkans and they emphasized the total inadequacy of the measures then available for the treatment and prevention of malaria. Largely through his continued interest in malaria in the Balkans Wenyon prevailed on Sir Henry Wellcome to support in this area a small laboratory, which under Dr Henry Fox has carried out much important work on blackwater fever. After having acted as consultant in malaria both to the British Salonika Forces and after 1918 to the Army of the Black Sea, Wenyon returned to the Wellcome Bureau of Scientific Research in 1920. For his war services he was made CMG and CBE.

When Sir Andrew Balfour became the first director of the newly founded School of Hygiene and Tropical Medicine in 1923 Wenyon naturally succeeded him as director of the Wellcome Bureau of Scientific Research and when in its turn the Wellcome Research Institution arose in the Euston Road he became its first director-in-chief as well as director of research in the Wellcome Foundation. In 1926 Wenyon published his treatise on medical protozoology—a manual for medical men, veterinarians and zoologists—which as was most justly due

was at once hailed as a standard work. The effort expended in compiling these two magnificent volumes seems largely to have exhausted his capacity for research, and thereafter he published little that was original. His time, however, was fully occupied. In addition to directing an important research institution he had become in 1920 an honorary secretary of the Royal Society of Tropical Medicine. It was largely as a result of his initiative and drive that Manson House was built and freed from debt, and his endeavours were also largely responsible for the present flourishing condition of the Royal Society of Tropical Medicine. In 1945 he was elected president of the Society, and in 1947 was awarded its Manson Medal. Since 1920 he had acted as a sectional editor of the *Tropical Diseases Bulletin*. It is thus hardly surprising that in the course of years he became a kind of final court of appeal on all matters protozoological. This entailed a constant stream of visitors to the Wellcome Bureau from the Commonwealth, the Continent, and the United States of America.

Wenyon received many honours in addition to those already mentioned. In 1927 he was elected a Fellow of the Royal Society. He was also an associate member of the Société de la Pathologie Exotique, and in 1933 became an officer of the Legion of Honour. In 1945 he was elected an honorary life member of the New York Academy of Sciences, and in 1946 the American Society of Tropical Medicine awarded him the Theobald Smith Gold Medal. Finally, in 1947, he was elected an honorary fellow of the Royal Society of Medicine.

Although Wenyon made no outstanding medical discovery—his most important were probably the differentiation of *Endolimax nana* from other intestinal protozoa and the discovery of two of the five intestinal flagellates of man—yet he will have an assured place in the history of medicine. He it was who, with his old friend Professor Brumpt, still happily with us, first established protozoology as an essential branch of medical parasitology. Under his aegis the Wellcome Bureau of Scientific Research became internationally known. As the director of a scientific institution he can have had few equals, for he possessed in no uncertain degree the by no means common knack of invariably keeping "a happy ship." Those who worked with him will recall his, 'Well! I don't know I'm sure. What?'

In 1944 Wenyon retired from the Wellcome Research Institution but continued to act as consultant in tropical medicine to the Wellcome Foundation. For many years he had been collecting notes and material for a second edition of his *magnum opus* but only a few days before his death he had reluctantly informed his publishers that to accomplish his task was beyond his strength. It is to be hoped that younger hands will be enabled to bring his work to its final fruition.—G M F

PERCIVAL P COLE, OBE, MB, FRCS

After a long and trying illness Percival Pasley Cole died in London on Oct 19.

Percival P Cole was born at Weymouth on March 4, 1878 and educated at Weymouth College. He entered Guy's Hospital in 1897 as a dental student and qualified in 1899. He decided to become medically qualified, and obtained the Conjoint diploma in 1904. He held several house appointments at Guy's Hospital and took the FRCS in 1906. He then became lecturer in anatomy at Birmingham University and there he graduated M.B., Ch.B. in 1909. On his return to London Cole first worked as demonstrator of anatomy at the Middlesex Hospital, and then quickly obtained several hospital appointments, becoming surgeon to Queen Mary's Hospital for the East End in 1911, surgical registrar at the Cancer Hospital in the same year, and assistant surgeon to the Dreadnought Hospital the following year. He maintained his connexion with these three hospitals to the end, becoming senior surgeon to Queen Mary's Hospital in 1932 and consulting surgeon in 1938. At the Cancer Hospital he was appointed assistant surgeon in 1920, surgeon in 1922, and consulting surgeon in 1946. He became full surgeon at the Dreadnought Hospital in 1919, consulting surgeon in 1947, and vice-president in 1948.

Cole's early dental training may have accounted for his interest in plastic surgery, and throughout the 1914-18 war he was honorary surgeon to King George's Hospital, Waterloo.

and in charge of maxillo facial cases and he was also on the staff of the Brook War Hospital. At this time he published several articles on war injuries to the face and jaws, on other types of war wounds and injuries, and on reparative surgery.

Percival Cole was also greatly interested in the Seamen's Hospital Society and he was surgeon to the Dreadnought Hospital for thirty five years and surgeon to the Tilbury Hospital from 1930. He must have operated upon thousands of merchant seamen and as a result of his care many men who might otherwise have been lost to the Merchant Navy were restored to full duties. In recognition of his work in this connexion the National Union of Seamen in 1946 made him an honorary life member of the Seamen's Union. Cole was

(Kilgill and Fry Ltd)

the first member of the medical profession ever to be accorded this honour. As recently as July of this year he was made a vice president of the Corporation of the Seamen's Hospital Society, which was the highest honour that Corporation could bestow. He recently took part in the preparation by the Board of Trade of the eighteenth edition of the *Ship Captain's Medical Guide* which originally dates from 1868.

From 1926 Cole was consulting surgeon to the Bethnal Green Hospital, and he served on the executive council of the Institute of Hygiene from 1931. He continued in that capacity in the present Royal Institute of

Public Health and Hygiene. He was Hunterian Professor of the Royal College of Surgeons in 1918 and a member of the Association of Plastic Surgeons. He was awarded the OBE in the New Year's Honours List of 1947.

Cole was specially interested in several branches of surgery. For many years he was the chief exponent in this country of the filigree operation for inguinal and other herniae. In fact he was one of the early pioneers in the use of non absorbable monofilament sutures. He advocated and used this type of suture when many others were still doubtful of its value. Before the days of radiotherapy he brought relief to many cases of cancer of the uterus by his patient application of the 'cold cautery'. His skill as a first-class cancer surgeon and his wide knowledge of plastic surgery benefited many cases of the most distressing types of cancer. He was a competent and pleasant teacher and devoted much time and thought to the organization of postgraduate courses for ship surgeons. Throughout the British Commonwealth hundreds of his residents and postgraduate students remember him with gratitude and pride. During and since the second world war he continued his indefatigable work till well over the age at which he could have retired and those who sought his counsel found knowledge and wisdom and a sure grasp of affairs remarkable in a man over 70 years of age.

Although his passage through life was sometimes turbulent, Cole was always fearless and single minded. His friends, colleagues and associates found him easy to approach and received from him a ready sympathy combined with a wide sense of justice and a tolerance for others which won for him a lasting admiration and affection. The sympathy of all his many friends will be extended to his son and daughter by his first wife and to his widow, Dr Pearl Greene of the Marie Curie Hospital.

Mr E T C Milligan writes: The passing of Percival P Cole removes from the surgical world a colourful figure and leaves a sad gap in a wide circle of friends. His sayings and writings were a delight, for he had the gift of the picturesque word, the polished phrase and deep feeling. It was perhaps easier for him to share his plans and ideas than his heart. He had strong views and rigid opinions and for these he fought in the face of opposition and at the risk of criticism. No one was better fitted to champion the new revolutionary treatment

of hernia by filigree. At the Dreadnought Hospital in the early part of this century he learnt the operation from Lawrence McGavin. He saw in it a method which alone in those days could deal successfully with a sailor's hernia and return him to sea. P P never wavered in his assessment and appreciation of this operation, and while new fashions followed one after another he maintained his confidence and enthusiasm for the filigree method. He practised it, taught it, and had it filmed—a film which should be preserved as a record of successful pioneering work, for now surgical opinion is no longer unkind to the filigree and buried metal.

Usually, as surgeons mature, wider visions for closer human and world relationships call them. The scientific world of surgery alone ceases to satisfy their heart's longings. Percival Cole, however, maintained his interest in surgery and surgical technique at white heat, so that the planning and execution of his jaw and face surgery, his filigree repair of the largest hernias, and his bold operations for cancer continued to be done with finished artistry and tenderest touch. His individual concern and care for sick merchant sailors of all nations through the Seamen's Hospital Society were an inspiration to his colleagues. He showed that through medicine it was possible to surmount the antipathies of class, colour and nations. We will remember him as a man who knew what he fought for and loved what he knew. P P gave an inspiring lead and was a great fighter.

Dr Henry Robinson writes: Percival Cole was the junior and the last survivor of the surgical team which in the second and third decades of the century drew visitors from far and near to the clinics and the operating theatres at the Royal Cancer Hospital—the others of the sextet were Charles Ryll, Ernest Miles, Jocelyn Swan, Cecil Rowntree, and Cecil Joll. While all were first rate general surgeons several of them had special interests—Miles in proctology, Swan in genito urinary work, Joll in thyroid and gastric surgery. Cole's special line was plastic surgery in which he got ample opportunities of serving his generation in both the two great wars. No doubt his early training as a dental surgeon was of value in facial reconstructions, but apart from this he had a real flair for this specialty and had both the imaginative boldness in planning and the deftness in execution which plastic surgery requires. He was a consistent exponent of Arbuthnot Lane's "no touch" technique, which he practised as admirably as Lane himself. Cole was a good committee man and a born chairman, though he suffered fools not very gladly and could be rather tart if he thought nonsense was being talked, he knew how to keep a meeting to the point and not allow it to wander off into side issues. He was of athletic frame and had been good at several games, notably lawn tennis.

#### SIR BRUCE BRUCE-PORTER KBE CMG, MD DL

Sir Bruce Bruce-Porter died on Oct 15 at the age of 79 at the home of his son-in-law and his daughter in Somerset. Harry Edwin Bruce-Porter was the son of the late Capt J Porter RA and was born at Woolwich. He was educated privately and at the London Hospital where he won many prizes and scholarships. He qualified as LSA in 1892 and took the Conjoint diploma in the following year. He then joined the Army Medical Staff as it was called and won more distinctions at Netley. After rising to the rank of surgeon captain he resigned and began private practice in the West End of London. As Dr Bruce-Porter he was soon well known, and at one time had probably one of the largest and most lucrative general practices in London. He was one of the men who were quick to appreciate the value of the young science of clinical pathology. His opportunity for distinction came with the war of 1914-18 when he was recalled to service and promoted to command the Third London General Hospital where he found himself at the head of a team of the leading London consultants. Later he went out to Mesopotamia in command of No 40 British General Hospital was mentioned in dispatches and awarded the CMG in 1917. He had also done good work as physician to King Edward VII's Hospital for Officers.

Outside his strictly professional work Bruce Porter had many interests and made himself very useful. He was a Deputy-Lieutenant for London, a Fellow of the Institute of Public

Health, a member of the Council of the Imperial Service College Trust, a military member of the Council of the Territorial Force Association of London a past president of the Hunterian Society a vice president of the Shaftesbury Society and Ragged School Union an honorary member of the Smeatonian Society of Civil Engineers and a Knight of Grace of the Order of St John of Jerusalem. He served also on a Home Office committee charged with inquiry into legislation on the treatment of inebriates. He founded the Bruce Porter Home for children of Dr Barnardo's Homes needing orthopaedic treatment. In 1919 then a colonel in the Army Medical Service he was honoured for his services by the conferment of the K B E. In later years he joined forces with Sir Arbuthnot Lane in the latter's New Health Society.

Sir Bruce married in 1896 Essie daughter of the late Rev D Bruce D D, of Auckland New Zealand and widow of J H Honeyman, M D. They had twin daughters. Lady Bruce-Porter was a Lady of Grace of the Order of St John of Jerusalem and died in 1937. Bruce-Porter had been an early and keen devotee of motoring and was a founder-member of Brooklands.

Dr WILLIAM HENRY LEWIS, who died on Sept 24 at the age of 82 was born at Llansantffraid and lived and worked there all his life. A student at the University of Edinburgh, he graduated M B, C M in 1887, and was still only 21 when he returned to Llansantffraid and went into practice. In the course of forty two years in general practice Dr Lewis won the esteem and affection of thousands of patients. He retired from practice in 1929 and was then able to devote much of his time to local government. He had become a county councillor in 1919 and was for many years chairman of the public health committee and took a particular interest in the problems of mental deficiency tuberculosis and school medical services. He represented the county on the Court of the University of Wales and on the board of the Normal Training College, Bangor. He had been appointed a justice of the peace as early as 1904 and in recognition of his long service to the county he was appointed high sheriff of Montgomeryshire in 1935. Dr Lewis had two hobbies gardening and wood carving. He carved the reredos at Llansantffraid Church, and many notable examples of his carvings of furniture are still to be found in the district. Dr Lewis had been a member of the British Medical Association for almost sixty years and he served as president of the Shropshire and Mid Wales Branches in 1927-8. He was also vice president of the North Wales Society for the Blind.

Dr ARNOLD THOMAS DENSHAM the son of Henry Densham of Bristol died in London on Oct 13 at the age of 66. He was educated at Clifton College and St John's College Cambridge. After leaving Cambridge he entered Guy's Hospital and the Royal Ear Hospital. Densham entered the Indian Medical Service and remained abroad until invalided out in 1909. The disability which led to his resignation was deafness following diphtheria contracted while attending a patient. Densham did not feel justified in continuing medical work under such a disability, the difficulty in hearing heart and chest sounds was to his mind incompatible with medical practice although other work in the service had been suggested to him. Dentistry seemed to offer a branch of medical work which he could undertake and no doubt he was influenced in this choice by having a brother Ashley in the dental profession whom he subsequently joined in practice. This entailed his return to Guy's Hospital in 1909 in order to take a dental qualification which he accomplished in 1911. Subsequently he held for some years the appointment of chief assistant in the dental department of St Bartholomew's Hospital. Densham had a sound knowledge of medicine was a good classical scholar and a knowledgeable man in many other respects, always able to give a sound and well-considered opinion. He used short rather than long words if equally applicable and had the gift of expressing much in a few clear and concise phrases. In this respect he resembled his uncle George Ernest Herman whose book on difficult labour was often quoted as a model of clear and concise language. Densham's sense of fairness and his integrity of character were shown in many ways during his life quite apart from his characteristic refusal to continue in a service in which he considered he was unable to give the best. Densham was a lovable character modest in every way and courteous in manner. His disability made it difficult for him to enter much into society but his friends and acquaintances were very appreciative of his fine and generous qualities. He was a bachelor and the youngest but one in a family of eleven.

Dr FREDERICK ROBERT DINGLE who died with tragic suddenness on Oct 2 at the age of 46, was a student at Guy's Hospital and qualified M R C S, L R C P in 1925. He went to Gateshead a few years later and quickly built up a large practice. His popularity as a doctor in a densely populated industrial area meant that he had to work very hard. During the war years, despite the added burden of being entirely without assistance, he did his full share in the work of the protection of practices scheme, and his obligations to his absent colleagues were most faithfully fulfilled. Dr Dingle still found time for outside activities in the medical field. He was chairman of the Gateshead Division of the British Medical Association in 1940-1, but perhaps his greatest outside interest was in his work for the Medical Institute in the sister borough of Newcastle upon-Tyne. He was treasurer of this popular doctors' club from 1937 until his death, and over this ten-year period there was a remarkable development in every field of the Institute's activities largely as a result of Dr Dingle's work. His early death will be deeply regretted not only by his many patients but also by his fellow practitioners in the North-east—J C A.

Dr ERIC OLIVER BLAKE died at his home in University Square, Belfast, on Sept 24 after a few months' illness. Dr Blake, who was a native of Trinidad, came to Belfast in 1922 and graduated there in 1927. Soon afterwards he started in general practice in the Newtownards Road district.

D B E writes Dr Blake will long be remembered by his many patients and friends for his kindness particularly to the poor, and for his devotion to duty. He was a good physician and one of the best type of general practitioner. The sympathy of his colleagues in Belfast will be extended to his wife and to the rest of his family.

Dr ALEXANDER BOYD ROBERTS, who died on Oct 7 at the age of 74 was in practice in Hammersmith and Maida Vale for thirty years before ill health forced him to retire in July of this year. In his native Canada he was better known as one of the intrepid men who led the Klondike Gold Rush in 1896. With his brother James he was among the first to cross the Chilkoot Pass, and at Lake Bennett they built their own boat, *The Clyde* one of the steadiest craft to run the Whitehorse. Roberts learnt to the full the dangers and hardships of the North and came from the Klondike with a life already packed with experience. Soon afterwards he began his medical studies, and graduated M D at McGill University Montreal, in 1902. He practised in Saskatoon until the 1914-18 war when he served in the C A M C and later in the R A M C. During the recent war he was medical officer to a first-aid post in Paddington where he gave invaluable service. In his work his greatest interest always lay with his patients. He was an outstanding general practitioner of the best type, and his enforced retirement was felt by his patients as a great loss to them all. He married Dorothy Brand-Hardy, of Beckenham Kent in 1916, and she and a married daughter in France survive him. His last years were clouded by the loss of his only son and younger daughter.

Dr LYSTER COLE-BAKER died at his home in Waterlooville Hants on Oct 14 at the age of 83. Dr Cole-Baker was born in Victoria Australia, and studied medicine at Trinity College, Dublin in London, and in Vienna. He graduated at Dublin in 1890 and proceeded M D two years later. He spent a year in practice in Maidstone before settling in Portsmouth, where for many years he was honorary ophthalmic surgeon at the Eye Infirmary and honorary surgeon at the Royal Portsmouth Hospital. During the 1914-18 war he was in charge of the Military Families Hospital there. Dr Cole-Baker is said to have been responsible for introducing the principles of aseptic surgery at the Royal Hospital. He was a frequent contributor to the medical press and published short articles in the *Journal* as long ago as 1901. He was one of the first doctors in the city of Portsmouth to own a motor-car and he had been a councillor for many years retiring only when he was appointed school medical officer at Waterlooville. During the second world war he joined the Home Guard, and was A R P casualty officer for his district. For many years Dr Cole-Baker was actively concerned with the Portsmouth Conservative Association and a member of the Royal Albert Yacht Club.

Dr CHARLES DUDLEY BISHOP who died on Oct. 17 at the age of 73 was one of the older generation of doctors in Wandsworth. A native of Clapham he was a student at Charing Cross Hospital and qualified in 1899. He remained in general practice throughout his lifetime and was held in great respect and esteem by his colleagues and his patients alike. Before the war he acted as honorary anaesthetist at the Bolingbroke and

Charing Cross Hospitals and his many years of service in that capacity are recalled with gratitude. As a younger man he took a keen interest in local medical affairs. He was a loyal member of the British Medical Association, which he first joined in 1901. He represented his colleagues at the annual representative meetings in 1925, 1926 and 1927, and was chairman of the Wandsworth Division from 1930-2. Though he continued in practice until recently, failing health curtailed his activities. In spite of that he contrived to be a regular attendant at the divisional meetings during the controversial months preceding the introduction of the National Health Service. His wife who died three or four years ago, was a chronic and almost helpless invalid and the devotion and care which he bestowed upon her were most touching. He was a genial, kindly man, a general practitioner in the best traditions of the old school and his familiar figure will be greatly missed.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

Sir Walter Hamilton Moberly, chairman of the University Grants Committee, will deliver the Rede Lecture in the Senate House on Thursday, Nov 18, at 5.30 p.m. His subject is 'Universities and the State'.

### UNIVERSITY OF LONDON

Dr H. R. Ing, D.Phil., will deliver a Special University Lecture on 'The Pharmacology of Homologous Series' at the London School of Hygiene and Tropical Medicine, Keppel Street W.C., on Friday, Dec 3, at 5.15 p.m. The lecture is addressed to students of the University and to others interested in the subject. Admission is free, without ticket.

The Semon Lecture for 1948 entitled 'Broncho oesophagology in Great Britain—the Decline of a Science. A Plea for Better Cooperation and Teaching' will be delivered by Mr G. Ewart Martin at the Royal Society of Medicine (1, Wimpole Street, London, W.) on Thursday, Nov 4, at 5 p.m. Special University Lectures on 'Rubella in Pregnancy as an Aetiological Factor in Congenital Malformations and Still Birth' by Dr Charles Swan (University of Adelaide) and 'Social Factors in Obstetrics' by Professor D. Baird (University of Aberdeen) will be delivered at Westminster Medical School (Meyers Lecture Theatre) Horseferry Road, London, S.W.1, on Tuesday, Nov 16 at 5 p.m. and Friday, Nov 26, at 5.30 p.m. respectively. The lectures are addressed to students of the University and to others interested in the subjects. Admission is free, without ticket.

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY—J. C. Bulstrode, J. G. L. Cole, J. C. A. L. Colenbrander, J. B. Latta, D. O. Connell, J. H. O. Connell, B. Stoll, R. D. St. G. Tucker, A. H. N. Velikala.

### UNIVERSITY OF LIVERPOOL

At a graduation ceremony held on Oct 15 the degree of Master of Radiology was conferred on J. R. MacLeod and D. E. Paterson.

### UNIVERSITY OF LEEDS

Stanley Jack Hartfall, M.D., F.R.C.P., Professor of Therapeutics and Applied Pharmacology, has been appointed to the Chair of Clinical Medicine in the University, in succession to J. Le Fleming C. Burrow, M.D., F.R.C.P., who has retired, and Louise Frances Winifred Eickhoff, M.D., D.P.M., has been appointed Senior Lecturer in Child Psychiatry.

### QUEEN'S UNIVERSITY, BELFAST

The first A. B. Mitchell Memorial Lecture was delivered at Queen's University, Belfast, by Professor G. Grey Turner, M.S., F.R.C.S., on Oct 19. His subject was 'Transplantation of the Ureters'.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

The Harvard Oration was delivered at the College on Oct 18 by Dr F. M. R. Walshe on 'The Structure of Medicine and its Place among the Sciences'. The Oration was printed in an abridged form in the *Journal* of Oct 23 (p. 753).

After the Oration the Weber-Parkes Medal and Prize were presented to Dr Stephen Roodhouse Glove. The prize is awarded triennially for the best work done on the aetiology, prevention, pathology or treatment of tuberculosis.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

The Annual Meeting of Fellows and Members of the College will be held at the College (Lincoln's Inn Fields, London W.C.) on Wednesday, Nov 10, at 5.30 p.m., when a report from the Council will be laid before the meeting.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct 9.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. *Figures of Births and Deaths and of Deaths recorded under each infectious disease are for—* (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales (London (administrative county) will no longer be published).

‡ Includes primary form for England and Wales (London (administrative county) and Northern Ireland).

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales (London (administrative county) are combined).

|| Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Discussion of Table

1. *England and Wales* increases were recorded in the notifications of measles 515, scarlet fever 39, and dysentery 26. There were decreases in the incidence of whooping-cough 131 and typhoid fever 22.

The largest rises in the notifications of measles were Lancashire 207 and Gloucestershire 76, and the largest fall was Yorkshire West Riding 51. No large fluctuations were reported in the local incidence of diphtheria or scarlet fever. The only variation of any size in the local trends of whooping cough was a decrease of 50 in Essex.

The chief centres of dysentery were Lancashire 28 (Liverpool 20) and Surrey 15. The largest returns for poliomyelitis were Yorkshire West Riding 11, London 9, Middlesex 6, Surrey 5, and Lancashire 5.

In *Scotland* an increase of 29 in the notifications of dysentery and a decrease of 13 in cerebrospinal fever and of 10 in diphtheria were the chief features of the returns. The largest returns of dysentery were Glasgow 57 and Lanark county 17. The fall in the incidence of cerebrospinal fever and diphtheria was due to the experience of the western area.

In *Ireland* increases were recorded in the notifications of scarlet fever 48, measles 40, and typhoid fever 10, a decrease of 11 was reported in the notifications of diarrhoea and enteritis. The rise in the incidence of scarlet fever was due to the experience of Dublin C.B. A further 55 cases of measles were notified from the outbreak in Clare K. Rush R.D. where 28 cases were notified in the preceding week. The 12 cases of typhoid fever were scattered through nine areas, the only multiple notification was 4 cases in Kerry, Dingle R.D.

In *Northern Ireland* a decrease of 13 was recorded in the notifications of scarlet fever. In Belfast C.B. a rise of 33 occurred in the notifications of measles, while the incidence of whooping cough declined by 11.

## September Quarter, England and Wales

In the weekly return of the Registrar-General for England and Wales for Oct 16 provisional rates are given for the September quarter. The infant mortality was 28 per 1,000 live births, and was the lowest rate ever recorded for any quarter. The previous lowest was 31 in the June quarter of this year. The stillbirth rate at 22.6 per 1,000 total births was 0.1 below the preceding lowest level. The birth rate was 17.7 per 1,000, a fall of 1.3 compared with the rate of the preceding September quarter. The general death rate was 9.4 showing a rise of 0.5 on the rate for the September quarter of 1947.

## Week Ending October 16

The notifications of infectious diseases for England and Wales during the week included scarlet fever 1519, whooping cough 1949, diphtheria 141, measles 4536, acute pneumonia 479, cerebrospinal fever 36, acute poliomyelitis 81, dysentery 114, paratyphoid 9, and typhoid 12.

## Medical News

## Gastro-enteritis Flying Squad

The Hospital for Sick Children, Great Ormond Street, London has formed a flying squad of trained nurses with a medical man in charge to help in the treatment of cases of infantile gastro-enteritis in hospitals or institutions. The squad is available to visit any hospital that desires its help and it is fully equipped to augment the existing nursing arrangements or to set up a special unit. The squad was formed on Nov 1, and the squad can be obtained through the local medical officer of health or regional hospital board, or in emergency by telephoning the house governor of Great Ormond Street Hospital (Holborn 9200) who will give any further information required. The scheme is being partly financed by the King Edward's Hospital Fund and has the good will of the Ministry of Health.

## Dose Table

The Dose Table (August 1948) has now been issued in accordance with the N.H.S. (General Medical and Pharmaceutical Services) Regulations. It lists the provisions relating to the calculation of doses for drugs and appliances supplied to N.H.S. patients.

## Medical Women's Federation

The Medical Women's Federation is now Taffstock, 11 Tavock Square, London W.C.1 (Tel. Euston 1111).

## Metallic Contamination of Foods

The Ministry of Food states that the Food Standards Committee, whose appointment was announced by the Minister of Food in January, has set up a subcommittee to inquire into the metallic contamination of foods. The subcommittee is invited to consider (a) the available evidence of the effect of the ingestion of foods contaminated with metals or other injurious elements, (b) the possibility of prescribing limits of contamination, and (c) the technological problems which might arise from the prescription of such limits. The following have agreed to serve on the subcommittee: Mr G. G. Barnes (Chairman), Dr L. E. Campbell (Director, British Food Manufacturing Industries Research Association), Professor G. R. Cameron (University College Hospital Medical School), Professor S. J. Cowell (Medical Research Council), Dr J. M. Johnston (Department of Health for Scotland), Dr W. P. Kennedy (Ministry of Health), Dr G. Roche Lynch (Senior Official Analyst, Home Office), Dr J. R. Nicholls (Department of the Government Chemist), Mr G. T. Taylor (Public Analyst), Dr G. W. Monier-Williams (formerly in charge of Food Research Laboratory, Ministry of Health). The subcommittee is asking research associations, food processing firms, and medical and technical associations to co-operate in the inquiry. In particular the subcommittee wishes to know (i) the metals and the foods which have been the subject of investigation, (ii) the period covered by the investigation, (iii) the units of measurement used to express the degree of contamination, (iv) the analytical method adopted. Persons or organizations who are able to supply such data and who have not already been approached are invited to write to Mr K. R. Allen, Secretary of the Food Standards Committee, at the offices of the Ministry of Food, Food Standards Division, Devonshire House, Mayfair Place, Piccadilly, London, W.1.

## Queen's University, Belfast

Latest published figures show that the amount raised for the Queen's University Centenary Endowment Fund is almost £300,000. The target figure was a quarter of a million. The Vice-Chancellor, thanking the Nuffield Provincial Hospitals Trust for its donation of £30,000 to endow a Chair and Department of Child Health, said: "The creation of the new Chair will make possible the development and integration of teaching and research facilities which exist in the hospitals associated with the University. In addition the Belfast Corporation is to make available to the University facilities for study and teaching in the child-welfare clinics. This co-ordination should advance the development of 'positive health' and result in great gain to the undergraduate teaching and postgraduate research."

## Association of Certifying Factory Surgeons Dinner

At the annual dinner of the Association of Certifying Factory Surgeons, which was held at the Café Royal on Oct 20, several speakers mentioned the necessity for teamwork between management, labour, and industrial medical officers. Dr R. Nightingale, the President, in proposing the toast to the Factory Department of the Ministry of Labour said that industry had never cried louder for help and guidance about health. There was a greater future for the certifying factory surgeon, now to be called, unfortunately in his opinion the appointed factory doctor. Replying to the toast Mr G. A. Isaacs, Minister of Labour and National Service, said that the fight of the trade unions to obtain improved health conditions in industry was won with the help of the doctors. The aim was now to build up a national industrial medical service properly integrated with the National Health Service. The toast of the Association was proposed by Mr G. P. Barnett, Chief Inspector of Factories, and in reply Dr H. W. Patterson said that he was glad that certifying factory surgeons were the legitimate children of the Ministry of Labour and the Home Office—but there was a wicked uncle in the background, the Ministry of Health. They did not want to be lost in the jungle of the various new health organizations which were being set up, and he was grateful for the help the Association had received from the B.M.A. The toast of the visitors was proposed by Dr C. L. Graham, and Professor R. E. Lane and Dr A. J. Amor replied.

## Union of St Luke

The Union of St Luke has issued its first "Periodical Letter" (price 1s). Particulars may be obtained from Dr R. H. Hardy, 5c, Park Hill Road, London, N.W.3. The Union was founded this year as an association of Anglican medical men and women.

## Mobile Clinics and Centres

A circular from the Ministry of Health to local authorities draws their attention to the use of mobile dental clinics and of mobile centres for maternity and child welfare. Various local authorities have been using suitably equipped vehicles for these purposes in the more remote areas where permanent centres cannot yet be provided, and information about their experience with them may be obtained from the Ministry.

**Medical Clerk of a City Company**

On completion of 21 years' service as Clerk of the Worshipful Company of Glaziers and Painters of Glass, Major General R J Blackham A M S (ret.), has been unanimously elected an Honorary Member of the Court of Assistants—the governing body of the Company—and presented with an antique clock and a cheque by the Court and Livery of the Glaziers Company, which is distinguished from other City Guilds by representing a branch of art and not a division of industry. So far as is known General Blackham is the only medical man who has ever been Clerk of a City Company with the exception of the late Group Captain Cooper, who was Clerk of the only medical Guild—the Society of Apothecaries.

**Mule Spinners' Cancer**

The Manchester Committee on Cancer has recently distributed to all practitioners in the neighbourhood of the Lancashire and Cheshire cotton mills a brief account of epithelioma of the skin as it affects mule spinners which has been prepared by Dr E M Brockbank. Copies are also being distributed at the request of employers and workers in some of the mills, the intention being to encourage spinners to report at the earliest stage any affections of the skin.

**Wills**

Dr James McIntosh, formerly professor of pathology in London University and director of the Bland Sutton Institute of Pathology at Middlesex Hospital left £19,978. Dr Alfred Walter Sikes formerly a divisional medical officer in the public health department of the London County Council and lecturer in physiology at King's College left £10,298.

**COMING EVENTS****Federation of Committees for the Moral Welfare of Children**

The Federation of Committees for the Moral Welfare of Children (13, Gray's Inn Square, London, WC1) has arranged a conference to be held at Caxton Hall, Westminster, London, SW, to day (Friday, Oct 29), at 2.30 p.m., when Dr Lilius M B Jeffries will speak on 'Marriage in Our Time', preceded by an exposition of 'Our Work in Action' by committee members and a children's worker. There is a conference fee of 1s, payable on admission.

**Princess Alice Emergency Hostel for Mothers and Babies**

Princess Alice Countess of Athlone, will open officially the Princess Alice Emergency Hostel for Mothers and Babies at "Castlebar," 46 Sydenham Hill, London, SE, on Tuesday Nov 2 at 3.30 p.m.

**Edinburgh Lectures**

In connexion with the postgraduate courses in medicine and surgery the Edinburgh Postgraduate Board for Medicine has arranged a series of open lectures on subjects of wide biological interest which began in the West Medical Lecture Theatre of Edinburgh Royal Infirmary on Oct 12. Further lectures details of which will appear in the diary column of the *Journal*, will be given on Nov 2 and 23 and Dec 7 and 21. The lectures are open to all graduates and students.

**Royal Dental Hospital of London School of Dental Surgery**

The annual clinical "At Home" of the Royal Dental Hospital of London School of Dental Surgery will be held at the Royal Dental Hospital (32, Leicester Square, London, WC) on Saturday, Nov 27, at 3 p.m. The dinner of past and present students of the hospital will be held at the Savoy Hotel at 7 for 7.30 p.m. the same day.

**SOCIETIES AND LECTURES****Saturday**

KENT PAEDIATRIC SOCIETY—At Maidstone Town Hall Oct 30, 2.30 p.m. *The Insecure Child* by Miss L M Rendel. *Know Your Baby* film.

**Monday**

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY 330-2, Gray's Inn Road, London, WC—Nov 1, 2.30 p.m. *Facial Paralysis from the Otolological Standpoint* by Miss Dorothy J Collier.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE Keppel Street WC—Nov 1 5.15 p.m. *Enzymatic Break down of Proteins (II)* by Professor K Linderstrom Lang (Copenhagen).

SOCIETY OF APOTHECARIES OF LONDON—In the Hall Black Friars Lane Queen Victoria Street E.C. Nov 1, 5 p.m. *The Constitutional Factors in Psychological Medicine* by Dr Eliot Slater.

SOCIETY OF CHEMICAL INDUSTRY—Joint meeting of Food Group and London Section at Royal College of Science Huxley Building Exhibition Road South Kensington London SW Nov 1, 2.15 p.m. Symposium *Aspects of Packaging with particular reference to the Food Industry*.

**Tuesday**

CHADWICK TRUST—At Sir Edward Meyerstein Lecture Theatre Westminster Hospital Medical School, 17, Horseferry Road Westminster, London, SW, Nov 2 2.30 p.m. *The Prevention of Tuberculosis with special reference to Environment* by Dr Wyndham E B Lloyd.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Edinburgh Royal Infirmary (West Medical Lecture Theatre) Nov 2, 5 p.m. *Cirrhosis of the Liver* by Professor J W McNee.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square London, WC—Nov 2, 5 p.m., *Histopathology of the Skin* by Dr I Muende.

INSTITUTE OF UROLOGY—At St Paul's Hospital Endell Street London, WC, Nov 2 11 a.m., *Manifestations of Secondary Syphilis* by Dr W N Mascall, 5 p.m., at St Peter's Hospital Henrietta Street London, WC, *Fistula of the Bladder (Acquired)* by Mr F R Kilpatrick.

ROYAL STATISTICAL SOCIETY RESEARCH SECTION—At E.L.M.A. Lighting Service Bureau, 2, Savoy Hill, London, WC Nov 2 4.30 p.m. *Some Statistical Problems Arising in Genetics* by Professor J B S Haldane, FRS.

SOCIETY OF APOTHECARIES OF LONDON—In the Hall, Black Friars Lane, Queen Victoria Street, E.C. Nov 2 5 p.m. *Use of Sex Hormones in Therapeutics* by Dr Peter Bishop.

UNIVERSITY COLLEGE, Gower Street, London, WC—Nov 2 1.15 p.m. *Process of Learning in Octopus* by Professor J Z Young, FRS.

**Wednesday**

EDINBURGH CLINICAL CLUB—At Edinburgh Royal Infirmary (Ward 34), Nov 3, 4 p.m. *Leucorrhoea* by Dr E C Fahmy.

INSTITUTE OF UROLOGY—At St Paul's Hospital Endell Street London WC, Nov 3, 11 a.m., *Skin Eruptions of Secondary Syphilis* by Dr A H Harkness 5 p.m., *New Growths of the Bladder (Benign)* by Mr C H Mills.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION—At B.M.A. House, Tavistock Square, WC, Nov 3, 8.30 p.m. *Criminal Courts and the Doctor* by Mr Claude Mullins.

LONDON COUNTY MEDICAL SOCIETY—At Lambeth Hospital, Brook Drive, SE, Nov 3, 3 p.m. Clinical meeting.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE 28 Portland Place, London, W—Nov 3, 3.30 p.m. *The Planning of a Modern School in Relation to the Public Health* by Mr S Johnson-Marshall, B Arch, A R I B A.

**Thursday**

EDINBURGH ROYAL INFIRMARY—Nov 4 5 p.m. *Corcinoma of Rectum* Honyman Gillespie Lecture by Mr Robert Muir.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street Leicester Square, London WC—Nov 4, 5 p.m., *Complications in Eczema* by Dr G B Mitchell Heggs.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY 330-2, Gray's Inn Road London, WC—Nov 4, 2.30 p.m. *Diseases of the Aurum of Dental Origin* by Mr J Angell James.

INSTITUTE OF UROLOGY—At St Paul's Hospital Endell Street, London, WC Nov 4 11 a.m. *Skin Diseases Simulating Secondary Syphilis* by Dr A H Harkness, 5 p.m., *New Growths of the Bladder (Malignant)* by Mr C H Mills.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY—At London Jewish Hospital, Stepney Green E, Nov 4 3 p.m. *The Aesthetics of Vision* Presidential address by Mr Harold A Levy.

LONDON UNIVERSITY—At Royal Society of Medicine, 1, Wimpole Street, London, W, Nov 4, 5 p.m. *Broncho oesophageal injury in Great Britain—The Decline of a Science A Plea for Better Cooperation and Teaching* Semon Lecture by Mr G Ewart Mar in.

ST GEORGE'S HOSPITAL MEDICAL SCHOOL Hyde Park Corner London, SW—Nov 4 4.30 p.m. *Neurology and Psychiatry* Lecture demonstration by Dr Anthony Feilding.

**Friday**

LONDON CHEST HOSPITAL Victoria Park, E—Nov 5 5 p.m. *Surgery of the Oesophagus* by Mr V C Thompson.

LONDON UNIVERSITY—At University College (Anatomy Theatre) Gower Street, WC, Nov 5, 5 p.m. *Relations of Interdependence between Various Parts of the Nervous System in the Embryo and in the Adult* Special University Lecture (in French) by Professor G Levi (University of Turin).

ROYAL INSTITUTE OF PHILOSOPHY—At University Hall 14 Gordon Square London WC Nov 5, 5.15 p.m. *Morality and Art* by Professor T E Jessop.

ROYAL MEDICAL SOCIETY, 7, Melbourn Place, Edinburgh—Nov 5 8 p.m. Debate.

SOCIETY OF APOTHECARIES OF LONDON—In the Hall Black Friars Lane Queen Victoria Street, E.C, Nov 5, 5 p.m. *Endocrinology and its Relation to Diagnosis and Therapeutics* by Professor E C Dodds.

## A new applicator for Volpar Paste

A specially designed Volpar Applicator is now available for those patients who prefer to use Volpar Paste instead of Volpar Gels. This method is particularly suitable for use in hot climates.

Volpar preparations have been prescribed and used on an increasing scale throughout a decade and abundant evidence of their efficacy, acceptability and innocuousness has been produced.

Descriptive literature is available, on request.

## FOR THE BUSY PRACTITIONER

The convenience of tablet medication is undoubtedly of marked value in the treatment of many conditions presented daily to the physician.

This is particularly true of alkaline therapy, where 'Milk of Magnesia' Tablets are a frequent and everyday prescription. In the busy dispensary, or for providing immediate symptomatic relief while visiting the patient's home, they present advantages readily appreciated by the practitioner.

Quickly dispensed, accurate in dosage and convenient to take during working hours, 'Milk of Magnesia' Tablets offer a simple yet efficacious means of combating gastric upset due to hyperchlorhydria.

### SPECIAL PROFESSIONAL PACKS

For personal surgery or dispensing use, a professional pack of 'Milk of Magnesia' Tablets is available. This contains 500 Tablets and costs 10/- (including tax) post free. Orders should be sent direct.

Each tablet contains approximately 0.5 grains of magnesium hydroxide ('Milk of Magnesia' brand).

## 'MILK OF MAGNESIA' TABLETS

THE CHAS. H. PHILIPS CHEMICAL CO., LTD., 1, WARPLE WAY, LONDON, W.3

★ 'Milk of Magnesia' is the trade mark of F.H. preparation of magnesia.

**What's New . . .****for Adults****DAYAMIN CAPSULES**

For multiple vitamin therapy, providing a rational dietary supplement in cases of vitamin deficiency. Of high potency and concentration, each Dayamin capsule contains vitamins A, B<sub>1</sub>, B<sub>2</sub>, B<sub>6</sub>, C, D, Nicotinamide and Pantothenic Acid, and supplies more than the minimum dose of most of the vitamins present. Can be taken at night without interference to digestion.

**for Infants and Children****VI-DAYLIN**

The children's multi vitamin preparation containing vitamins A and D, Aneurine Hydrochloride, Riboflavin, Ascorbic Acid and Nicotinamide combined in an extremely palatable syrup. Ideally adapted for administering the daily vitamin supplement to infants and children.

**PLAIN TALKS ON INFANT FEEDING**

## Let us Give Thought to the Amino-Acids

As every doctor knows, the nutritional value of proteins depends on their amino-acid composition and grouping. Here Humanised Trufood scores spectacularly for a comparison between the amino-acids in mother's milk and in Trufood reveals a very close approximation. (*A detailed comparison of percentages is given in a special leaflet which is sent free on application*) The significance of this approximation hardly needs emphasising. Since the quantity of casein is reduced, and the amino-acid content is brought into approximation to that of human milk by building up the soluble proteins, it means that the young child prospers on Trufood with the same ease and success as it does on mother's milk. This statement is proved by the experience of countless mothers and the observation of welfare officials. *Literature giving detailed information can be obtained by writing to Trufood Ltd (Dept BM30), Bebington, Wirral, Cheshire.*

*Issued by the Makers of Trufood—*

**NEAREST TO MOTHER'S MILK**

## APPOINTMENTS

Norman Fraser Mackenzie, M B, Ch B, Dipl Psych, has been appointed Medical Superintendent of Newchurch Homes, Culcheth. He will also be responsible for the medical supervision of the smaller mental deficiency establishments in the Region and for advising on mental deficiency problems.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

## Para-aminosalicylic Acid

Q—In the Journal of July 17, 1948 p 148 the treatment of pulmonary tuberculosis by para-aminosalicylic acid is discussed. Are there any contraindications to trying this drug on any case of tuberculosis? If so what are they?

A—Lehmann introduced para-aminosalicylic acid as a result of experiments *in vitro* which suggested that it inhibited the growth of the tubercle bacilli by interfering with its metabolism. Favourable results have been reported by some authors in the treatment of exudative types of the disease and in tuberculous empyema. So far clinical trials have not been sufficiently extensive to prove the value of this drug, but the Medical Research Council is shortly to institute a controlled trial of its value. Until the results of this trial are known, indiscriminate use of the drug should be discouraged.

## Chronic Tuberculous Cystitis

Q—What is the modern treatment of tuberculous cystitis? Should transplantation of the ureter into the rectum be considered in a patient who has had one kidney removed and in whom the cystitis remains obdurate?

A—The treatment of chronic tuberculous cystitis still remains a most difficult problem. Such a case as that mentioned should certainly have a course of tuberculin (T R). In some cases instillation of (not irrigations with) a 6% aqueous solution of carbolic acid will relieve symptoms, and, if cystoscopy should show these to be due to localized ulceration, much benefit often ensues from the use of high-frequency diathermy to the ulcer. In this case, as one kidney has already been removed and the infection still persists, grave suspicion attaches to the remaining kidney. Under these circumstances transplantation of the ureter would carry a high risk of superimposing secondary infection. In these cases, if transplantation is considered justifiable (and it often is) the skin is preferable to the bowel. Presumably it is frequency rather than pain that worries the patient. If pain were excessive pre-sacral neurectomy might be considered.

## Preventing Abortion

Q—A patient who married at 39 became pregnant but aborted at the fourth month. Now five months later she has again missed a period and is probably pregnant. Syphilis and uterine displacements have been ruled out as have the usual other well-defined organic causes. It is important that she should have a living child. (a) Are there any measures which should be adopted by the patient in addition to the usual precautions such as rest and avoidance of alcohol, excessive sexual intercourse, strain, etc? (b) Is treatment with progesterone justified and if so in what doses and for how long? (c) Does vitamin E help to improve her chance of completing a successful pregnancy?

A—The occurrence of one abortion previously is not very significant, but in view of the circumstances of the case it is undoubtedly wise to take all reasonable precautions. It is not enough to ban excessive sexual intercourse; coitus should be avoided completely. Vitamin E can do no harm, although its value in these cases is disputed. If given, a large dose—20 mg tds—of alpha-tocopherol is recommended. Thyroid, 1 gr (65 mg) daily, might also be given empirically. Progesterone therapy is probably best avoided unless there is some evidence of a deficiency of this hormone. Such evidence might be obtained by estimation of the output of pregnanediol. This test is carried out on a 24 hour or first morning specimen of urine (depending on the technique) and is undertaken by only a few laboratories in this country. If the pregnanediol excretion is low it would be wise to give 10 mg progesterone intramuscularly two or three times weekly, starting immediately and continuing until the 28th or 32nd week of pregnancy. For further

on pregnanediol tests and progesterone therapy in antenatal and habitual abortion reference should be made to article by S Bender which appeared recently in the *British Medical Journal* (1948 1 683) and to an annotation in the same issue (p 696)

### Inheritance of Deformities

**Q**—Is termination of pregnancy justified in a case where the only child now 11 years old has gross congenital deformities? In the case I have in mind the mother was normal until four weeks from term when she developed generalized oedema. At birth there was a breech presentation with extended arms and legs both fibulae were absent and there was valgus deformity of the feet. What is the likelihood of the mother giving birth again to a child with congenital abnormalities?

**A**—This type of congenital deformity seems to occur sporadically at least in the great majority of instances, and there seems to be little evidence that heredity is a factor of importance. It is true that there appears to be a general tendency for a woman who has had a deformed child to have a somewhat increased chance of bearing another—not always with the same type of deformity. The increased risk is a small one, however, and the chance that the present pregnancy will result in a deformed child is probably not much greater than the 1 in 40 or so for any random pregnancy. The mother can be reassured that the odds are heavily on the side of the child, and in the writer's opinion abortion could not be justified on genetic grounds.

### Use of Detergent Solutions

**Q**—What is the usual composition of proprietary liquid detergents? Can you tell me if there is any danger in contraindication to their use for the following purposes (a) washing of dishes and other domestic utensils and (b) personal ablution?

**A**—It is not possible to discover the composition of a detergent which is a proprietary preparation. Many detergents, however, have similar properties, and it is a general rule that there is little danger from their use in washing dishes and utensils. For personal ablutions, however, they may give rise to dermatitis in sensitive subjects. Very severe dermatitis has followed the use of detergents as hair shampoos.

### Paronychia

**Q**—Can you suggest any effective treatment for a woman aged 42 with a chronic paronychia of 7½ months duration? There is a slight discharge of pus containing staphylococci every month or so and a kaolin poultice gives relief on these occasions which are of short duration. In the intervals the skin around the nail fold remains swollen and the nail has become wrinkled. Operation is not indicated.

**A**—If ringworm and monilial infection have been excluded as causes of the paronychia, treatment should aim at keeping the part dry, using radiant heat or short-wave diathermy locally or fractional doses of x rays and the following paint:

R Mercury perchloride	1%
Brilliant green	1%
Spirit	ad 100%

Make a paint

An impaired peripheral circulation may play a part in the aetiology in which case small doses of phenobarbitone and thyroid are helpful.

### Adolescent Obesity

**Q**—A girl of 18 has put on 1½ st (95 kg) in weight during the past twelve months. One sister (thirteen years older) was obese when much younger; there is no other family tendency to obesity. There is little evidence of over-eating except perhaps that she is a little too fond of sweets. Do girls in the late teens often tend to put on weight for a year or two? What investigations are necessary and what is the most likely cause?

**A**—It is more usual for the weight to be put on in the early teens—that is at and after puberty—and for some of this to be lost in the later teens. The writer who believes that adiposity is due to hyperactivity of the pituitary and adrenal glands rather than to any endocrine deficiency considers that this increase in weight is associated with greater activity of the pituitary gland.

at this phase in people of certain endocrine constitution. In the absence of other endocrine stigmata it is unlikely that investigations would reveal any gross lesion in this patient. Apart from an endocrine constitution as indicated above, one can only speculate on other causes, and that to no great purpose.

### Hot Flashes

**Q**—Is there any treatment for repeated hot flashes and sweats? A woman aged 53 who has had four children, was well until 1943 when her uterus was removed for fibroids. In 1944 she had acute rheumatism which left her with mitral stenosis. Her blood pressure has gradually increased until now it is about 200/105 mm. The hot flashes and sweats average about thirty a day and leave her exhausted. No treatment has had any effect.

**A**—It would be helpful to know what treatment has been tried. If the flushes and sweats are menopausal, as seems likely, they should respond to oestrogens. If they do not, then either the diagnosis is incorrect or previous oestrogen therapy may have been badly planned so that the patient has become resistant to it. Unless previously tried without effect, oestrogen should be given according to the usual technique, starting with the smallest possible dose which is sufficient to control rather than eliminate the flushes, and then gradually reducing this dose over the course of two or three months. Alternatively empirical treatment with a tocopherol 60 to 100 mg daily or large doses of calcium, or small doses of thyroid, might be tried. The usual remedies for hypertension—rest and phenobarbitone, etc.—should be applied simultaneously. Symptoms of the kind described sometimes have a psychological basis.

## NOTES AND COMMENTS

**Unauthorized Quotation**—The solicitors to the Medical Defence Union have asked us to publish the following letter from Messrs H B Wedlake Sant and Co. "On behalf of our clients, Silten Limited, of Silten House, Hatfield, Herts, we refer to your letter of Sept 24. Our clients have noted that you have been consulted by Professor L S P Davidson and Dr J J R Duthe with regard to the use by our clients of your clients' names and the quotation from the section of the book on the treatment of rheumatic diseases written by your clients, in connexion with our clients' preparation Leucotropin. Our clients appreciate that it is considered grossly improper for a member of the medical profession to be associated with the sale of a proprietary remedy, and express their sincere regret that the pamphlet circulated by them gives the impression that your clients were advocating the use of our clients' preparation and are the authors of our clients' pamphlet. Our clients admit that the use of the names of your clients was unauthorized and fully apologize for the improper use of their names and the unauthorized quotation from the book written by your clients. Our clients undertake to withdraw the pamphlet from circulation forthwith and to destroy all pamphlets in their possession and to pay the costs incurred by your clients. Our clients have noted that your clients reserve to themselves the full right to publish this apology in the medical press or in such other manner as may be necessary to undo the harm which is likely to result to them from the improper use of their names."

**Guide to the B.P.**—British Drug Houses, Ltd. has recently published a new edition of its *B.D.H. Guide to the B.P. 1948*. It is available free to members of the medical profession. The purpose of the *Guide* is "to direct the attention of physicians and pharmacists to the alterations which have been made in the new Pharmacopoeia, with particular reference to the articles and preparations which are different from the corresponding ones in the 1932 B.P. and to those which have become official for the first time."

**Correction**—In the letter from Dr M J Fenton in the *Journal* of Oct 16 (p 723) there was a misprint in the name of the substance used for the treatment of burns—the correct name of the substance is silver dinaphthylmethane disulphonate.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 30 1948

## NATIONAL HEALTH SERVICE TRAINING GRANTS FOR ASSISTANTS

The Ministry of Health has published details of the arrangements under which grants will be available to general practitioners in the new Service for supervising the training of assistants. Practitioners who wish to apply for a training grant and who satisfy the conditions laid down should apply to the local executive council. Any practitioner on the medical list whose application is approved by the local medical committee, which is augmented by two members nominated by the university for the area of the regional hospital board, is entitled to one of these grants. The grant will amount to £150 a year plus a sum not exceeding £700 a year in respect of the assistant's salary, boarding expenses, and employer's contributions for superannuation and national insurance. If an additional car is necessary, a further allowance not exceeding £150 a year may be made. The conditions governing payment of the grant to approved applicants are

(a) The assistant employed must not have been previously in general practice in the British Isles (otherwise than for a short period as a locum tenens)

(b) The period of training will be one year, and accordingly the grant may not be paid for more than one year in respect of the same assistant. Where the arrangement between the principal and the assistant is terminated before the year is up, the circumstances should be reported to the local medical committee.

(c) The doctor will not be entitled to a grant in respect of more than one assistant during the same period. (He may, however, employ an assistant in the ordinary way at the same time as an assistant for whom a training grant is being paid.)

(d) The doctor must have not less than 2,000 patients on his list. He will not be entitled to increase his list of patients beyond the usual maximum (e.g., 4,000 for a single-handed doctor) in respect of an assistant for whom a grant is paid.

(e) The grant will be payable from the date on which the assistant takes up the appointment, notification of which should be sent to the executive council by the principal, or the date on which approval of the training grant is notified (if the appointment has been made beforehand).

A principal whose application is approved will himself be responsible for appointing the trainee assistant and for satisfying the executive council that the assistant appointed has not previously been in practice in the British Isles.

### Employer's Share Criticized

The principal will be required to pay the employer's share of the contributions due in respect of the assistant under the National Insurance Scheme (4s 2d a week) and the Health Service Superannuation Scheme (8% of salary). The Ministry's contention is that the employer's share of these contributions will come out of the £700. This has been strongly criticized by the profession's representatives. The effect is to reduce the maximum of £700 to under £640 less the assistant's own share of national insurance (4s 11d a week) and superannuation contributions (6% of remuneration). For superannuation purposes the assistant's remuneration includes the money value of board and lodgings but does not include travelling expenses. It was represented to the Ministry that the principal would not be permitted to increase his list beyond the usual maximum, that the £700 he receives will be passed on to the assistant, possibly with an addition by himself, that in earlier announce-

ments no hint had been given that the grant would be subject to these deductions, and that a trainee should be regarded as a student rather than an employee.

The Ministry supports its contentions by pointing out that an experienced assistant gets £700 to £800 and that a trainee assistant should get less. The Ministry argument runs thus:

If the salary were £650 the cost to the principal would be £650 plus 8% plus £11 (N.I.), or £713. At £640 the cost would be £702 but the £63 or £62, as the case may be, would be practice expenses and rank for income-tax allowance.

An assistant getting £650 would have to pay £51 in superannuation and national insurance contributions, leaving roughly £600. In his case, too, the contributions would be allowed in assessing income tax.

### Information about Principals

Executive councils have been asked to confer with the local medical committees on the information which should be supplied in connexion with an application for the training grant—e.g., the name of any partner or other assistant, the number of patients on the practitioner's list or on that of any partner or assistant, the practitioner's qualifications, and the salary, etc., which it is proposed to pay to the trainee assistant.

Payment of the training grant will be made quarterly by executive councils. Special forms will be provided on which principals will claim the quarterly payment, the claim being countersigned by the trainee assistant.

## GRANTS FOR G.P. REFRESHER COURSES

*The Ministry of Health has issued a memorandum describing the arrangements made in England and Wales for providing refresher courses for medical practitioners serving in the N.H.S. (under Section 48 of the N.H.S. Act 1946) and for medical men released from H.M. Forces who before recruitment were engaged in general practice. The Ministry's scheme is described below.*

The courses for which financial assistance is available are those advertised by universities and medical schools as specially arranged for general medical practitioners and consisting of 11 or 22 half-day sessions, either intensive or spread over a number of weeks. In addition, a special concession is being continued for ex-Service doctors. Those who prefer to return to their medical schools and attend their teaching hospital selecting such undergraduate teaching and clinical practice as they most need, or who avail themselves of similar postgraduate facilities offered by their university may claim reimbursement of expenses within the scales laid down.

### Procedure for Claiming Grant

**National Health Service Doctors**—A general medical practitioner who is taking part in the National Health Service can claim a grant under these arrangements for attending either one course of 22 sessions or two of 11 sessions each if

(a) at least three years have elapsed since the date of his first registrable qualification,

(b) he has not less than 500 (or in the case of a rural practice 250) persons on his National Health Service list, or on his combined

lists if he is under contract with more than one executive council (in the early days of the National Health Service doctors with smaller lists of not less than 300 persons or in a rural area 150, may qualify),

(c) he has not within the previous year already received financial assistance under the Government scheme for doctors released from H M Forces or under the Government scheme for National Health Insurance doctors or National Health Service doctors (this condition may be waived in exceptional circumstances)

A National Health Service doctor who wishes to attend a course and to claim this grant should send a form of application for grant (Form G P R C 2) as long as possible before the course starts to the postgraduate dean or director of the university. The university will, if prepared to accept the applicant, transmit the application for grant to the Ministry of Health who will as soon as possible tell the doctor, the executive council(s) with whom he is in contract, and the university whether the application for grant is approved.

**Ex-Service Doctors**—A doctor who was before recruitment engaged in general practice can claim grant—also for attending either one course of 22 sessions or two of 11 sessions each—if

(a) he applies to attend a course or courses within twelve months of his demobilization,

(b) he has not within the previous year already received financial assistance under the Government scheme for doctors released from H M Forces or under the Government schemes for National Health Insurance doctors or National Health Service doctors (this condition may be waived in exceptional circumstances)

The Ministry of Health's prior approval is not needed in these cases. If a doctor satisfying the conditions is accepted by the university he automatically qualifies for grant.

#### Extent of Financial Assistance

**Course Fees**—A doctor who qualifies for grant is normally not concerned with the payment of the course fees. A contribution in respect of these is made direct by the Ministry to the university concerned. If, however, under the special arrangements mentioned in the first paragraph an ex-Service doctor is charged a fee he may claim reimbursement from the Ministry of Health (on Form G P R C 3) up to a maximum of 10 guineas for 22 sessions and *pro rata* for shorter courses. It is understood that normally the fees would be much below this and that sometimes no fee may be charged.

**Subsistence Allowances Travelling Expenses, and Locum Fees**—The following expenses may be reclaimed by a doctor who qualifies for grant, whether he is a National Health Service doctor or is applying as an ex-Service doctor.

(a) subsistence allowances up to £1 a day if attendance necessarily entails absence from home at night or otherwise actual expenses up to 5s a day,

(b) travelling expenses (e.g. at first class monthly return rates where the course necessarily entails absence from home at night)

(c) payment of a locum tenent where necessary up to a maximum of 14 guineas a week.

Details are set out in the form of claim (Form G P R C 3) which should be completed by the doctor as soon as possible after the end of the course and forwarded to the postgraduate dean or director (or other university official through whom the course was arranged) who would certify that the doctor had attended the course and transmit the claim to the Ministry of Health.

#### S.M.A. AND HEALTH CENTRES

The following resolution was passed by the Council of the Socialist Medical Association on Sept 26

The Council of the Socialist Medical Association welcomes the recognition by the Council of the British Medical Association of the need for health centres. The Socialist Medical Association supports the urgent demand put forward for an experimental trial of different types of health centre in varying areas, but is strongly opposed to the view that widespread development of health centres should not be commenced until after such experiments are completed. The further development of general practice depends on health centres and these in accordance with the Act must be set up and properly equipped by the local health authorities and not left to individual groups of practitioners, whose association would not be under democratic control."

## INSURANCE ACTS COMMITTEE

### BIRTH PANGS OF THE NEW SERVICE

A meeting of the Insurance Acts Committee was held on Oct 7 Dr E A Gregg presiding. A long report was placed before the Committee on matters which had been dealt with since July 5 by the General Practice Subcommittee of the Negotiating Committee. In dealing with the first matter, partnership agreements in relation to compensation, the chairman of the Negotiating Committee (Dr Dain) said that representatives of the Association had given evidence before the Legal Committee on Partnerships, and the witnesses had been recalled to answer further questions. The discussions had been most friendly and understanding. The report of the Legal Committee was expected very shortly.

Nominations for the chairman and six members of the Medical Practices Committee had been forwarded to the Ministry of Health, and the nominees had been appointed. Dr Dain mentioned that great difficulty had been experienced in finding persons willing to serve on this body.

#### Distribution of Practitioners' Funds

It was reported that two Distribution Committees had been set up, one to determine the apportionment of the Central Practitioners' Fund between England and Wales and Scotland and the other for England and Wales. Here again the nominations made had been accepted by the Ministry. Apparently it would be necessary to wait until the end of the year before the distribution could be rationalized. Several members of the IAC complained of the retention of too much money at the centre. The chairman said that the Distribution Committees had done their best in view of the many problems connected with this matter and the Ministry was going to press on executive councils the urgent necessity of completing this work.

A document was distributed to the Committee showing for each area the applications for basic salary, the number approved also the amount per patient received by executive councils from the central pool, and the amount paid to general practitioners. The high proportion of applications for basic salary in some areas was a matter of comment, and it was urged that the Committee should issue to local medical committees a statement pointing out the reasons for requiring full information of an applicant's income, professional and private, before a decision could fairly be reached in each case.

In some discussion on basic salary it was suggested that the bulk of the profession still entertained the idea that basic salary was freely optional. A London member asked how basic salary could justifiably be given without some reference to the practitioner's total income. Was it to be given to the practitioner with the small list and the large private practice or to the semi-retired who needed only a small income? He read a letter on the subject which had been sent out by the London Local Medical Committee in which the following paragraph appeared:

'The basic salary is in effect a subsidy to one practitioner paid by his colleagues in the area. The onus of showing reasonable justification therefore falls upon the applicant.'

It was agreed that a similar letter be sent out from the Committee to the chairmen and secretaries of local medical committees.

#### Remuneration of General Practitioners

The Committee appointed a special subcommittee to prepare a case for an improvement in the remuneration of general practitioners in the National Health Service.

#### Remuneration for Special Services

Attention was next drawn to the fact that in the interim terms of service under regional hospital boards it is pointed out that a doctor's capitation fee covers general practitioner services given to a patient on his or his partner's list, whether the services are rendered in hospital or not, but that in order to furnish remuneration for hospital work for other patients a staff fund is to be created by a yearly payment of £25 for each occupied bed (other than pay beds), the fund to be shared among the general practitioner staff.

Members of the Committee said that in cottage hospitals, where general practitioners were doing work which in larger hospitals would be done by house-surgeons, though it could not be said to be specialist work, this £25 was completely inadequate to the time and energy expended. It was suggested that in the course of the next two years the cottage hospitals would cease to be staffed by general practitioners and would be used for special purposes. The opinion of the Committee that £25 was not sufficient for this purpose was recorded, and it was asked that the matter be reopened with the Ministry with a view to the amount being increased.

On the question of the Special Inducements Fund (a sum equal to 1% of the Central Practitioners' Fund to provide inducement payments to assist doctors to practise in peculiarly difficult areas), Dr Dain said that this was extra money, and he impressed on representatives from rural areas where this fund might properly be used that it was important that advantage should be taken of it.

On fees for specialist services by general practitioners Dr Dain pointed out that there was a difficulty here which the Ministry had not appreciated when drawing up the regulations, and the problem of the provision of payment to general practitioners for specialist work would receive further consideration.

### Rural Practice

It was announced that after consultation with the Rural Practitioners Subcommittee the Ministers' offer of 6s 6d per annum as the dispensing capitation fee had been accepted without prejudice to revision after negotiations at a later date.

The report of the Rural Practitioners Subcommittee, presented by Dr J C Pearce, also recommended that, in order to implement the Spens Report in its reference to rural practitioners, county local medical committees should be asked to classify all practitioners entitled to mileage payments into three groups—namely, urban (meaning small towns), semi-rural, and rural—and that the ordinary portion of the mileage fee be distributed among these three categories in accordance with a progressive scale of units which was set out in the recommendation. This was approved.

The position of rural practitioners in relation to local obstetric lists was considered, and it was resolved to call the Ministry's attention to instances where a doctor had been admitted to the local obstetric list in one area but refused in another, and to press for payment of mileage in appropriate cases in connexion with maternity medical services.

### Medical Treatment of Overseas Visitors

Among several other matters relating to the new service which came under discussion was the question of overseas visitors and foreign seamen being allowed to take advantage, without payment of the National Health Service during their stay in Great Britain. It was stated that a protest had been lodged against a public announcement of this concession being made without previous consultation with the medical profession. It was also considered that the legality of this concession was dubious, for the Act in Section 1, says

*It shall be the duty of the Minister of Health to promote the establishment in England and Wales of a comprehensive health service designed to secure improvement in the physical and mental health of the people of England and Wales.*

Overseas visitors can hardly be regarded as 'the people of England and Wales,' and counsel's opinion on the subject is to be sought.

It was agreed that the report (which had occupied most of the day) covering the matters dealt with by the General Practice Subcommittee of the Negotiating Committee should be incorporated in the annual report of the IAC, published in the Supplement of Oct 16. The formidable agenda of the meeting, which occupied both morning and afternoon was not completed, and certain matters were held over until the next meeting of the Committee on Nov 11 also an all-day meeting.

While the meeting was proceeding the Minister of Health was addressing the executive councils in the adjoining hall, and certain points of his speech were retailed to the Committee. He stated that 18 165 general practitioners had entered the service together with 80% of the dentists and that 90% of the population had registered. He appealed to doctors to use discretion in prescribing.

## CENTRAL CONSULTANTS AND SPECIALISTS (INCLUDING HOSPITALS) COMMITTEE

The main discussion at a meeting of the Central Consultants and Specialists (including Hospitals) Committee held at B M A House on Sept 30 centred round the 'Specialist' Spens Report (*Journal* June 12, p 1146). The Committee, which is now almost fully constituted, consists of more than 60 members, and there was a full attendance. Mr A M A Moore was voted to the chair for the meeting, the appointment of a permanent chairman being postponed till a later meeting.

In considering the Spens proposals for the remuneration of specialists attention was turned first to the question of the betterment factor. The Committee was reminded that general practitioners had been given a betterment factor of 20% and it was unlikely that a higher figure would be suggested by the Minister of Health for specialists. Another adjustment, in a different direction would have to be made in respect of the Government's contribution to superannuation, consultants having previously made their own provision for retirement. The net increase, after allowing for the betterment factor on the one hand and reducing by the superannuation factor on the other, seemed likely to be about one-ninth on the figures set out.

### The Starting Salary

The fear was expressed in one quarter of the Committee that the proposed starting salary of £1 500 for a specialist appointed to the staff of a hospital at the age of 32 was so low that an undue proportion of the best men would be attracted instead to general practice. A man entering general practice at the age of 23 or 24 might become a principal or a partner by the age of 27 or 28. It was pointed out that if such a general practitioner secured the maximum of public remuneration at the age of 28—an unlikely event—he would be receiving an income of £3 000, which would be subject to a deduction of from 35 to 40% for practice expenses. The Chairman of Council said that the average general practitioner would earn only about £2,000, and that it was necessary to correct the idea that the average general practitioner would be earning £3 000 at the age of 32.

Some discussion took place on the question of the starting age. One view was that a specialist could not be regarded as fully trained until he had reached the age of 32, and that it was not desirable as one member had suggested that a man at the age of 27 should be holding a responsible hospital post. As against this it was stated that a doctor could qualify at 23 and get his Fellowship four years later, at which time he should be entitled to rank for the full starting salary.

The Spens proposal that a specialist appointed to the staff of a hospital should receive a starting salary of £1,500 was agreed to, but it was also agreed that anyone found suitable for a similar post at an earlier age than 32 should be paid the full salary. It was considered that ex-Service specialists should receive specially augmented starting salaries. The increment proposal, that the salary should be augmented by an additional £125 after each year of service until a salary of £2,500 had been reached, was also accepted.

### Distinction Awards

The chief discussion of the afternoon centred around the proposal for merit awards, in three grades for selected specialists. Dr Cochrane Shanks, a member of the Spens Committee, explained that they were faced with the fact that there were variations in ability as between different specialists in the same hospital or region. Therefore it was suggested that there should be rewards of merit—in the first grade, of £2 500 a year in addition to the recommended salary, in the second grade, of £1,500, and in the third grade, of £500. 4% of all eligible specialists being awarded the first distinction, 10% the second and 20% the third. Dr Shanks considered this to be the most imaginative feature of the whole report. He could not think of any better method of encouraging initiative and endeavour. The award of £500 to the 20% of consultants would apply, of course, whether they had reached the £2,500 level or not. As a rule such men would be at the top of that ladder, though not necessarily so. In the highest

class the figure of 4% was taken, as against the statistical evidence of 5% before the war, because the Spens Committee had in mind that after the age, say of about 55 there was a definite drop in the earnings of consultants whereas a merit award, once given would be maintained at the full figure throughout the recipient's active professional career. The crux of the matter was in the choice of the people for such awards and the machinery favoured was a national committee chosen by professional bodies to make the final decision on recommendations received from specialist associations, the Royal Colleges, regional hospital boards, and boards of governors of teaching hospitals. An analogy was afforded by the F.R.C.P., where the Council chose the Fellows but was not allowed to nominate. An alternative to this proposal for merit awards would be to establish suitable established posts, but that presented a number of difficulties and the worst alternative of all would be an automatic ladder from the lowest scale up to the top.

Much difference of opinion was expressed in the Committee on this proposal. One member described it as fantastic, and another suggested that sufficient awards not necessarily monetary, were already available for the able consultant. It was doubtful whether the permanence of such awards was desirable. Some suggested that a better method would be to tie certain salaries to certain posts obtainable by the ablest men in open competition. Others supported the idea with reservations about the machinery by which the awards would be made. Eventually a motion disapproving of the principle of the merit award as laid down in the Report was carried by 26 votes to 21, with 7 abstaining.

It was suggested that alternative methods should be considered. The Committee however, decided not to proceed further with the matter at that meeting but to ask the Regional Committees for their comments generally and suggestions for alternative methods.

### Whole-time Service and Domiciliary Work

A further question for discussion was whether the whole-time consultant in the Service should be allowed to undertake paid domiciliary work. Several members suggested that domiciliary work should be undertaken by part-time specialists who should be properly paid for it. On the other hand it was pointed out that a good many whole time specialists were specialists in a certain narrow field and it was not right to deprive the community of their services so that the door should be kept open. Moreover in certain areas where it might be necessary to appoint whole-time officers there was no private practice of sufficient moment to attract part-time people to live in the district therefore some degree of domiciliary attendance must be provided. One view put forward was that a whole-time consultant was not employed in a hospital in the institutional sense of the word, but in a hospital service, which included domiciliary service.

It was agreed to refer this matter for consideration by the Regional Committees.

The Committee agreed to accept for the time being the mathematical formula set out in Para 7 of the summary of the Spens Report (relating to the computation of the basic remuneration of the part time specialist).

A special point arose on the question of income-tax deductions at source. It was stated that some young consultants had been embarrassed on receiving a cheque for little more than half the amount which they had expected. The point was strongly made that remuneration should be transmitted to the specialist without income-tax deduction. Consultants and specialists are not servants of the regional hospital board but are in contract with it, therefore like other outside contractors, they should be paid in full and include the payment subsequently in their private income-tax returns. It was agreed to make a representation to this effect to the appropriate authorities.

Finally, on the question of holidays the Spens recommendation was agreed to that specialists engaged in the Service should be entitled to definite holidays without financial liability for the provision of a deputy but there was a strong feeling that the specialist should have the right to appoint his own deputy.

Points deferred for consultation with the regions will come forward again at the next meeting of the Committee.

## Correspondence

### Needs or Demands

SIR—At a recent meeting of the London Executive Council (of the Health Act) a point of some importance was discussed in connexion with the adoption of the allocation scheme under the Act. The draft model scheme as drawn up by the Ministry for the consideration of executive councils provides that attendance at the patient's home shall be the duty of the practitioner "as may be required by him"—i.e. the patient. This ambiguous phrase can be construed to mean "according to his needs," or "if he so demands it." The London Executive Council felt that the former interpretation is the proper one and altered the wording to "as his condition may require," and this presumably is what the Ministry intended. Other executive councils may also have amended the scheme.

If any executive councils have adopted the model scheme without this correction it seems certain that before long trouble will arise with litigious patients, who will contend that they have only to "require" (i.e. demand) that the doctor shall visit them and that the latter is bound by his terms of service to comply.

It is very regrettable that the Ministry should have put out this phrase capable of two totally variant meanings and the representatives of the profession on executive councils all over the Kingdom would be well advised to take up the point with a view to amendment on the lines followed by London—I am etc.,

Tunbridge Wells Kent

HENRY ROBINSON

### Regional Specialist Committees

SIR,—It is only six months to the end of March, 1949 and many Regions have not yet formed a representative Regional Specialist Committee which can be certain that its delegates to the Central Committee really speak for the Region as a whole. In the Liverpool Region we have two Associations the Hospital Staffs Association and the Regional Hospitals Medical Association that between them cover the majority of the specialists working in the Region. These two bodies have sponsored a suggestion that the Liverpool Regional Specialists Committee be reconstituted as follows.

Two representatives to be nominated by the Liverpool University Faculty of Medicine.

Eight by the Hospital Staffs Association for the Teaching Hospitals.

Eight by the Liverpool Regional Hospitals Medical Association for the Regional Board Hospitals.

Two by the North-Western Branch of the Medical Superintendents Society.

Two by the Registrars, one to be from the Teaching Hospital Group and one from the Regional Hospital Group.

One from the Isle of Man.

This will give a completely representative committee, and we believe that all sections will feel satisfied.

We hope that anyone above the rank of house officer who is not already a member of the Regional Hospitals Medical Association if employed in a Regional Board Hospital will join us. We are most anxious that the old difference between voluntary and municipal hospitals should not reappear in a different guise in those now set up and we welcome the co-operation that we have received from the Hospital Staffs Association—I am etc.,

Liverpool Regional Hospitals  
Medical Association

Hon Secretary

### Constitutional Position of B.M.A.

SIR—At the Annual Representative Meeting at Cambridge this year the future organization of the Association was discussed with the result that Council appointed a Special Committee to inquire into the general question of the constitutional position of the Association. The Executive Committee of this Division is impressed not only with the importance of the matters to be discussed but is anxious lest the urgency of the position is not fully appreciated. It is obvious that there is unrest in the profession in regard to the B.M.A., and for

re at work which apparently seek to undermine its standing. One of this unrest might be alleviated if it were known that the committee mentioned above is now actively at work. This would indicate that B M A Headquarters is as alive to the issues at stake as are the rank and file of the profession—we are, etc.

A M POLLOCK  
Chairman

W O MOORE EDE,  
Secretary

Tunbridge Wells, Kent

MJ

### Capitation Fee

SIR—In the *Journal* of Oct 2 (p 663), under Medical Notes in Parliament, is published a reply of Mr Bevan's in which he stated that the total fund payable to general practitioners under the N H S was 18s multiplied by 95% of the civil population. On the same page is another of his replies stating (as late as Sept 23) that only 90%+ of the total civil population were already on the lists of doctors in the N H S. If, therefore, a sum of money allotted for 95% of the population has to be distributed on behalf of only 90% of the population, the individual capitation fee should become  $8s \times \frac{95}{90}$  or 19s per head of those now on doctors' lists. How is it then that this quarter some of us have received an amount equivalent to a 16s capitation fee and others as little as 15s?

Is the B M A going to accept this position without effective protest, or is it prepared to explain it away in the apologetic manner in which it has (?) explained away other controversial matters raised in the correspondence columns of the *B M J* as if it were now nothing more than the propaganda department of the Ministry of Health? Alternatively if the B M A is not prepared to protect our interests, is the general body of the medical profession so decrepit that it can do nothing but accept such 'pearls'?—I am, etc.

Newport Mon

C N COHEN

\* The Secretary of the B M A states: The capitation fee is calculated on an annual basis although payment to practitioners is made on a quarterly basis. It is true that if at the end of the year 90% of the population are on doctors' lists the remuneration per patient on doctors' lists would be proportionately higher than 18s for the year. Similarly, if 98% of the population were on doctors' lists the remuneration would be proportionately lower than 18s for the year. The quarterly payments are payments on account and subject to final adjustment at the end of the year.

SIR—The Spens Committee recommended that the capitation fee should be 15s odd in terms of 1939 values. It is generally agreed that the 1939 £1 is now worth 10s, thus the capitation fee should be 30s not 17s. The Government should be made to keep their promise—I am, etc.

Salisbury

PAUL HARRIS

### Delivery of Medicines

SIR—With reference to Dr W D Glynn Jones's letter (*Supplement* Sept 18 p 126) on the subject of the delivery of rural medicines under the National Health Service Act I think it may be helpful for me to report that having to deal with a similar difficulty in my own rural practice I referred this matter through my executive council to the Ministry and have secured permission to send medicines to patients living in remote districts by post at their expense.

The actual wording of the Ministry's statement is that, "If the patient requests the doctor to send the medicine by post, the Minister is advised that this should be regarded as a service outside the National Health Service, and a service for which the person supplied could properly be asked to pay. It is a great nuisance to have to pack numerous bottles of medicine and to get them to the post office but I do find my patients very ready to pay the 7d which an 8-oz bottle seems to cost for postage and to be very thankful indeed to be able to secure their medicines in this way. This does seem to afford one solution of a very considerable difficulty—I am, etc."

Dr W D Glynn Jones

A G CHAMBERLAIN

### Salaries of Opticians and G P's

SIR—As a corollary to Mr Stenhouse Stewart's letter (*Supplement* Sept 4, p 105) one can compare the remuneration of opticians and general practitioners. The optician is, I believe paid 15s for the examination of a patient. The £1 5s dispensing fee will cover his overhead expenses, rent, assistants' salaries, etc., so that on the basis of Mr Stenhouse Stewart's estimate of 12 patients in a six-hour working day he can working five days a week for 46 weeks, earn £2,070 a year. I need not stress the comparison with the recommended remuneration, responsibilities, and hours of work of a general practitioner—I am, etc.

Launceston Somerset

M J INGRAM

### Tell the Public

SIR—Is it not time that the B M A made use of the Press to inform the public of the terms of remuneration of doctors under the N H S, and the benefits to which the public are entitled whether State or private patients? When I inform my patients that I expect round about 15s per head per annum plus 2s 6d per hundred patients for the provision of small dressings, etc., and that I am obliged to pay all other practice expenses myself, I am flatly disbelieved. Yesterday I was told by a lawyer—whom one would expect to know better—that I was compelled to take on to my list anyone who applied—I am, etc.

Clifton Bristol

H K V SOLTAU

### The Interim Payment

SIR—I wish to place on record what happened when I applied on Sept 1 for an interim payment, as the Minister of Health gave an assurance in the House that any practitioners finding themselves in financial difficulties before Oct 1 could do so.

First, I had to write a letter stating why I was in financial difficulties. I then heard that a payment of 2s per patient on the list could be made—in my case, just starting a practice, this would be £14 10s for my 145 patients. This would not even pay the rent of my surgery, but I have not had it yet. I was also informed at the same time that the "approximately 18s per patient and basic salary of £300" had been reduced to 15s 2d for six-sevenths of the patients on the list if one was granted the basic salary. They could not tell me if my application for the £300 would be granted or not. What chance has a young practitioner in a new practice to earn a living?—I am, etc.

Bristol

K M A MILLARD

### Superannuation and N H S

SIR—Perhaps you could look over this. It is about superannuation and is worked out from the typical example No IV (i), p 24, in the booklet issued by the Ministry of Health, *Superannuation Scheme for Those Engaged in the National Health Service—An Explanation*. You will find there the case of Dr M, who pays in from age 35 for 30 years, when he retires. During this period his total net remuneration amounts to £36,000. Supposing his income is equally divided throughout the 30 years, he will have paid 6% of this amount, which is £2,160. Add interest at 2½% compound, which is £1,001. The State will have added 8%, which is £2,880. Add interest at 2½% compound, which is £1,335. So that if you were to go to the Ministry of Health vaults and open the cash-box marked Dr M, Code No M/42, you should find inside the sum of £7,376. Of course you wouldn't—I am told that this is purely a paper transaction and that there is really no money at all.

After two years of retirement Dr M dies (not an unlikely happening after at least 30 years in a busy practice). He will have drawn retiring allowance of £540 and £540 for each of the two years since retiring—total £1,620. By this time in the otherwise empty cash-box you would find a bit of paper marked 'Still to come, £5,756 plus interest'.

His widow, of the same age, now begins to draw her pension at the rate of £180 per annum. This ageing lady does her best and struggles on to see the thing through, and finally she and the cash-box become completely exhausted at the age of 100 (is this a record?).

So much for the State-added factor of 8% which we were encouraged to look upon as deferred salary—I am, etc.

Wallingford Berks

E J WARBURTON

### Revised Method of Payment

SIR,—At the end of the first quarter of the National Health Service it may be profitable to see how we stand. The doctors came in on July 5 on the terms which had been sent out to them and on condition that the Act was amended. Mr Bevan has not yet amended the Act and has thus broken his side of the agreement and the new regulations just received show certain changes adverse to the profession. The £300 grant is hedged round with conditions, is undependable as it may be withdrawn at any time, and is to be paid not out of State funds but as a first charge on the local practitioners' fund—that is, out of the doctors' pockets. Under such conditions many will rather go very short than apply. For the 4,000 and upwards panel the proposed scheme for assistants and special grants is not yet formulated and will be given only in special cases. Thus the inducements to enter the scheme are being withdrawn now that we are safely in. Payment for mileage and temporary residents is not yet settled, and the cheque (to account only) due on Oct 1 was not received until Oct 8.

The plight of those who depended mainly on private practice is apparently not appreciated by either colleagues or public. Payments by private patients have averaged about 45s per annum, and in many parts as many as 90% have joined the scheme in which the capitation fee is likely to be about 17s—a reduction of 28s per patient. Allowing for the few remaining private patients a loss of 50–60% of income has to be faced by the doctor—a very serious matter for those with families to feed and educate.

It is almost unbelievable that the B.M.A. would acquiesce in an arrangement that penalizes so heavily a large section of their members and I am certain that no other profession or trade would continue their work with a 50–60% cut in their pay. What is the B.M.A. going to do about it? The only adequate remedy is a sliding scale of capitation fee—30s for the first 1,000 patients, 25s for the second, and so on—paid automatically on the figures known to the executive council—I am, etc.

St Andrews Fife

M. K. DOROTHY DOUGLAS

\* \* An account of the scheme for trainee assistants is published in the *Supplement* this week at p. 149.—Ed. B.M.J.

### Piece-work or the Clock?

SIR—In the *Supplement* of Oct 9 (p. 134) Mr McFarland would like me to explain the relative disadvantage of the general practitioner to the consultant and specialist remuneration under the Spens Reports. May I therefore be allowed to explain that if the two Reports are compared it will be found that only 9% of general practitioners over 40 years of age will have a net income of over £2,000 p.a., whereas 33% of specialists can expect that income after this age? The specialists' advantage is so obvious that many of the most capable general practitioners are already considering how to switch over from general to specialist practice. This is precisely what the first Spens was afraid of—I am, etc.

Worthing Sussex

HAROLD LEESON

### Uneven Distribution of Patients

SIR—If 92% of the population have already registered with general practitioners there must be a very uneven distribution. It seems that the large panel practices of 2,500 before July 5 have a full list of 4,000 and the small practices are still small, and the newly established ex-Servicemen, trying to build or rebuild a practice have been left behind. The figures from the executive councils would be interesting. If my guess is correct, half the practitioners have far too many patients and the rest cannot find enough to pay expenses.

Another inevitable result of the present scheme is that children and old people are avoided to allow as large a proportion as possible of normally healthy young adults. Something must be done to rectify these defects and I suggest: (1) Lists to be limited to 1,500 composed only of men aged 15–65 and women 15–60. Capitation fee to be 25s for first 1,000 and 20s for subsequent 500. (2) Age groups 0–15 and over 60 and 65

for women and men respectively, to be treated on a fee-for-item-of-service basis as in private practice, i.e., 7s 6d. Accounts could be sent to patients quarterly certified correct by them and sent to the executive councils to the credit of the practitioner's account. These proposals would induce the practitioners with too many patients to take partners or release patients, and provide for much better attention for the very old and very young—I am, etc.

London W 8

CHRISTOPHER L. CARTER

### Basic Salary

SIR—The statement on basic salary (*Supplement* Oct 2 p. 131) illustrates only too clearly the lack of foresight in the Association's policy. Step by fellow-travelling step a course is set downhill to the detriment and shame of medicine. This statement is the latest, others leap to the pen.

(1) An agreement to a system of payment based solely on numbers can only lower the standard of service by one doctor to one patient. Is this B.M.A. policy?

(2) The failure to suggest any system of payment encouraging better service or skill. In fact, actual discouragement to render any service at all appears to be the main feature of the obstetric service.

(3) The promotion of friction between doctors forced by loss of income to apply for basic salary and those not so driven. Is the intention of the B.M.A. to unite or divide us?

(4) The complete failure to realize that there are two fixed pools—one numerical (patients), and the other financial.

There are many reasons of geography, health, age, to say nothing of conscience, which may debar a man from a large portion of the first pool, but an equivalent ratio of the second pool is a treachery to be "justified." This sermon on justification rings hollow in the ears of men prepared to work a decent service for a decent wage. It is no exaggeration to say that many doctors are confused and harassed by an immediate sense of frustration and a no less remote one of bankruptcy. We have been out-maneuvred in broad policy and outwitted in tactics, while professions auxiliary to medicine are amazed at their own windfall. Who will deliver us from this morass?—I am, etc.

Suton Surrey

L. GRAEME WILLIAMS

### Compensation for Wartime Changes in Practices

SIR—In 1939 many general practitioners conceived it their duty to join the Territorials or Volunteer Reserve of the Royal Navy or the R.A.F. in readiness for an expected *blitzkrieg*. Those who were under 35 had their duty clearly indicated to them at B.M.A. meetings. During their service they lost very heavily financially. The pay of a lieutenant (or flying officer) was about £380 a year, of a captain (or flight-lieutenant) about £430 and of a major (or squadron-leader) about £640 plus small marriage allowances where applicable, many had heavy civilian and family commitments to meet. They returned in 1945 or 1946 to sadly depleted practices (unless they were fortunate enough to have partners to look after their interests while they were away). In many cases there has been only one full accounting year since their return, in no case can there have been more than two years. It would obviously be seriously wrong to assess the value of their practices for compensation on these difficult first years of the post-war restart. It is understood that such cases will be specially considered, but they are so numerous, and so obviously entitled to fair play as a right and not as a concession that some general principle should apply.

I submit that the only fair assessment is to take the pre-war value of the practice and to add to it a proportion equivalent to the average increase from 1939 to 1947 of the value of the practices of those who, for good or bad reasons, remained behind. This proportion could easily be got out by the tax authorities, but I estimate that it is about 70%. Only so can these men who have been penalized for their war service by loss of income escape being further penalized for that service by assessment of their life's savings at figures which bear no relation to what their position would have been had they ignored the call in 1939—I am, etc.

London.

"PRE WAR V.R.

## POINTS FROM LETTERS

## No Other Course

Dr FILMER COLEMAN (Glenfield, Leics) writes I have been in times past a severe critic of the B.M.A. In fact, I resigned my membership years ago and remained a non member for about 20 years, but I don't like to read all the—to my mind—unfair criticism now being hurled at it. You can't build a house without putting down the foundations first, and so with the new scheme. It's no use talking of terms of service before the principles—the foundations—have been fixed. Surely the vote on the second (February) plebiscite was clear evidence that the profession agreed with the B.M.A. action in putting principles as the first and most important things to be settled. I think it would be more to the point if some complaint were made about the members of the profession who altered their vote at the third (April) plebiscite. I say altered their vote, because I didn't think many of them altered their opinion. If they did actually alter their opinion, I would still respect their honesty, though I might have doubts about their intellect. The B.M.A. on that vote could do no other than it did—viz., advise us to accept. On the personal side, Dr Guy Dain has seemingly been the target for mud slinging. I am certain he did his best—and a very good best too—for the profession. The one speech of his that I was fortunate enough to hear was by far the best of any I heard, but what could he do against the adverse vote but state that as the doctors had joined he would do his best to make the scheme a success? I don't suppose that he (Dr Dain) altered his vote at the last plebiscite. If the complaints are from those who voted against the scheme, my sympathies are with them in their let-down.

## Free Drugs for Private Patients

Mr DAVID HARDIE (Bournemouth) writes Dr R. Risk's letter (Supplement, Sept 18, p. 126) underlines a state of affairs which is bound to grow worse as people in general accept the really major attack on personal liberty embodied in the N.H.S. Hitler described the mechanism of this process in *Mein Kampf*. Dr Risk quite correctly points out that in this matter of free medicines an economic lever is being used to force a dissenting minority into the N.H.S., and those doctors who had the moral courage to stand up for their liberty against the loss of compensation threat are to be got at in this way. The real point is that the idea of compulsory social insurance is a totalitarian idea. Having swallowed the principles of the Devil, one can hardly be surprised if in action breach of professional confidence, and a further economic threat to protestants, are the immediate outcome, as seen in the power of the local bosses (embryo commissars) in the executive councils to inquire into the doctors' private incomes.

## Dispensing Fee in Scotland

Dr RUTH M. MONRO (Invergowrie, Nr Dundee) writes. Surely the agreement between the Ministry of Health and the Secretary of State for Scotland is still in force—that for payments in the Health Service the country shall be regarded as one and that there shall be no discrimination between England and Scotland. Yet in the first three months of the Health Service's existence this agreement has been broken. In England and Wales the capitation allowance for drugs to dispensing doctors has been raised to 6s 6d, in Scotland it is to remain at 5s. In the Health Service dispensing doctors are almost entirely limited to rural areas engaged in agriculture where there is no chemist. My practice lies in such an area and comprises 12 villages and a far greater number of farms and smallholdings. After nearly 15 years' experience of a dispensing practice I am convinced that it is impossible to provide first-class medication on an allowance of 5s per head. Without financial loss it can only be done by cutting down modern drugs to the barest minimum and using old-fashioned and less effective remedies or inferior quality of drugs. Patients will suffer and sickness will be prolonged. Every farmhand on the sick list affects the national larder adversely. The dispensing doctor gets no payment whatever for the actual work of dispensing and distributing medicine. At the present rate I estimate that I dispense about 5,000 prescriptions annually on an honorary basis. In addition there is the labour of keeping up stocks, preparing orders to manufacturing chemists unpacking crates of drugs and putting them away, repacking crates with empty containers and dispatching by rail. A chemist can do most of his stock-taking in working hours and do more after the day's visits and surgeries are done.

The Secretary of the Association writes. The Insurance Acts Committee on learning the position in Scotland, has expressed the view that there should be no differentiation in the dispensing fee and has requested its Scottish Subcommittee to reopen the matter with the Department of Health.

## Free Work or the Clock?

Dr H. J. PRATAP (Liverpool) writes. Mr John McFarland's letter (Oct 9, p. 134) says the tragedy of the remuneration with general practitioners is that the more money they get the

less actual medicine they do. The only types of cases referred to hospitals by general practitioners are cases of skin disease, ENT cases, and surgical and medical cases where hospital treatment is required that includes special investigation offered by hospitals only. The number of cases sent to hospitals in the above classes is not as large as Mr McFarland seems to imagine. Most of the cases in general practice are treated by the general practitioner.

At the first annual meeting of the Society of Clerks of Executive Councils held at B.M.A. House on Oct 6 Mr T. Crew, F.C.I.I., Clerk of the Leicestershire and Rutland Executive Council and Secretary of the Leicestershire and Rutland Local Medical Committee, was elected president for 1948-9.

**TRADE UNION MEMBERSHIP**

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton-le Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley

**BASIC SALARY IN SHEFFIELD**

The Sheffield Branch of the Socialist Medical Association has issued a statement protesting against the rejection of 29 out of 32 applicants for the basic salary of £300 in the Sheffield area. It says that 'one doctor who started in practice in May, 1948, and whose application for the basic salary was refused, already has 270 patients. At this rate of progress the doctor concerned will have considerably more than the minimum 500 on the list within two years. What can be the reason for rejecting that application? It can hardly be said that the doctor was not needed in that locality. No reasons for rejection are given in the letter sent to the doctors'. The statement continues that the local executive council may not have sufficiently inquired into the reasons which prompted the local medical committee to turn down so large a proportion of applicants. It points out that since the basic salary paid to doctors will reduce the sum available for the capitation fee to all doctors in the area it is perhaps unfair to expect doctors on the local medical committee to make these decisions. It is also unfair on the doctors applying for the basic salary that it should be possible for their colleagues to recommend rejection of their application and so make it more difficult for them to establish themselves in practice. The statement ends by asking the local executive council to reconsider the applications.

**H M Forces Appointments****ROYAL NAVY**

Surgeon Rear Admiral J. A. O. Flynn, C.B., has been placed on the Retired List.

Surgeon Commander V. G. Horan has been placed on the Retired List.

Acting Surgeon Lieutenant Commander J. A. N. Lock to be Surgeon Lieutenant Commander.

Acting Surgeon Lieutenant J. N. Cozens Hardy, O.P. Jordan and J. M. Alderton to be Surgeon Lieutenants.

**WOMEN'S FORCES****EMPLOYED WITH THE R.A.M.C.**

War Substantive Captain J. Harris has relinquished her commission and has been granted the honorary rank of Captain.

Lieutenants E. M. Knight, E. Power, R. Hamlyn, J. T. Smith, and C. E. Wildeboer to be Captains.

To be Lieutenants: Muriel T. McKenna, Doreen M. J. Stracey.

**INDIAN ARMY MEDICAL CORPS**

Captains R. T. M. Hayter, M.B.E., has retired and has been granted the honorary rank of Major.

**COLONIAL MEDICAL SERVICE**

The following appointments have been announced: J. E. Stobbs, M.B., S. O. Ekwuatu, M.B., and A. Zahra, M.D., Medical Officers, Nigeria; J. T. Burrows, B.M. M.R.C.O.G., Medical Officer (Specialist), Jamaica; W. S. Foster, M.R.C.S., Medical Officer (Health), Jamaica; R. B. S. Smith, M.B., D.T.M. & H. Assistant Director of Medical Services, Northern Rhodesia; L. G. W. Urlich, M.R.C.S., D.T.M. & H., D.P.H., Deputy Director of Sanitary Services, Trinidad; K. K. Kapadia, M.B., Medical Officer, Seychelles; C. C. Chahia, M.D., Medical Officer, Kenya; H. T. Lavcock, M.B., Medical Officer (Surgical), British Somaliland; E. S. M. Douglas, L.R.C.P., Acting Medical Officer, Jamaica; R. J. A. Lavoipierre, M.D., D.T.M. & H., Deputy Director of Medical Services, Mauritius; J. P. O'Mahoney, M.B., B.A.O., Chief Medical Officer, Barbados; A. A. Peat, M.B., Director of Medical Services, Trinidad; E. V. Strisiver, M.D., F.R.C.S., Medical Officer, Special Grade, Sierra Leone; C. E. E. Stevens, M.B., B.A.O., Superintendent, Cunningham Hospital, St. Christopher, Nevis; C. H. Tomlinson, M.B., Radiologist, Medical Department, Jamaica; H. G. Page, O.B.E., F.R.C.S., M.R.C.O.G., Surgeon Specialist, Grenada, Windward Islands.

**Association Notices****KATHERINE BISHOP HARMAN PRIZE**

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1949. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine.

The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1948.

**MIDDLEMORE PRIZE**

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1949 to the author of the best essay on "The Value of Orthoptics in the Treatment of Squint." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec. 31, 1948. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1949.

**Branch and Division Meetings to be Held**

**LEWISHAM DIVISION**—At Lewisham Hospital, 390 High Street, London, S.E., Friday, Nov. 5, 8.30 p.m. Dr. H. S. Banks, Fever Quiz.

**PORTSMOUTH DIVISION**—At Kimbells Corner House Restaurant, Commercial Road, Portsmouth, Tuesday, Nov. 2, 8 for 8.30 p.m. Dinner-meeting. Dr. E. M. Darmady, 'Modern Treatment of Uraemia'.

**RICHMOND DIVISION**—At Royal Hospital, Richmond, Tuesday, Nov. 2, 9 p.m. Mr. Richard J. V. Battle, 'Plastic Surgery'.

**WESTMINSTER AND HOLBORN DIVISION**—Joint meeting with Chelsea and Fulham and Kensington and Hammersmith Divisions at Postgraduate Medical School of the Royal Cancer Hospital, 24 Onslow Gardens, Fulham S.W., Wednesday, Nov. 3, 8.30 p.m. Mr. Ronald W. Raven, 'Cancer of the Pharynx and Oesophagus'. Open to all medical practitioners in the area of the Divisions.

**WOOLWICH DIVISION**—At St. Nicholas Hospital, 79 Tewson Road, Plumstead, London, S.E., Tuesday, Nov. 2, 7.30 to 9 p.m. Clinical cases followed by lecture by Dr. W. G. Tillman, 'Skin Diseases in General Practice'.

**Meetings of Branches and Divisions****GUILDFORD DIVISION**

At the meeting of the Guildford Division of the B.M.A. on Oct. 4, an address was given by Mr. Edward Jones, M.P.S., chairman of the South West Regional Health Committee and chairman of the Health Committee of the Corporation of Guildford on the 'National Health Service Act and the Practising Pharmacist'. He said that the Act had greatly increased dispensing, in Guildford during July the number of prescriptions increased by 129% and in August by 132%. Chemists' receipts had fallen at present, but they might rise later owing to the increased number of prescriptions dispensed, although of course at a lower cost than previously. Speaking of the provision of appliances, Mr. Jones said that closer liaison between chemists and doctors would be of immense value as the chemist was in a position to tell the doctor what he could get and what not. He gave as an example a prescription for a motor-driven chair—which of course could not be complied with. Illegible prescriptions caused more difficulty than ever owing to new drugs having very similar names.

The suggestion that periodic meetings between doctors and chemists be arranged was put as a resolution and carried. Mr. Jones dealt with many questions very ably and was thanked by the chairman of the Division.

## ETHINYL OESTRADIOL

BY

T N A JEFFCOATE, MD, FRCSEd, FRCOG

URSULA M. LISTER, MD, MRCOG

BETTY HARGREAVES, MB, ChB, MRCOG AND H ROBERTS, MB, ChB, DObstRCOG

(From the Department of Obstetrics and Gynaecology University of Liverpool)

Ethinyl oestradiol is an orally active oestrogen first prepared by Inhoffen and Hohlweg (1938). It is a derivative of alpha oestradiol, the chemical structure of the two substances being very similar.

It has already received quite an extensive clinical trial, particularly in the USA, but has not been available in this country until this year. Reports on its biological actions and therapeutic value have been published by Clauberg and Ustun (1938), Salmon and others (1941), Groper and Biskind (1942), Soule (1942, 1943), Watson (1942), Lyon (1944), Allen (1944), Harding (1944), Bickers (1946), Wiesbader and Filler (1946), and Birnberg and others (1947). These deal with its effects in women, and indicate that ethinyl oestradiol behaves like other oestrogens in its effect on the female genital tract and breasts, including relief of climacteric symptoms and suppression of lactation. Other reports, such as those by Lawrence and Werthessen (1942), Kearns (1942), Huggins and McDonald (1945), and McCrea (1946) go to show that ethinyl oestradiol also has the expected effect on conditions in the male such as carcinoma of the prostate and haemospermia.

Ethinyl oestradiol has reached this country with an already established reputation for being an effective oestrogen and, moreover, one which even when administered orally is extremely potent. Estimates of its activity vary considerably, but all observers agree that it is the most potent oestrogen so far discovered. Inhoffen and Hohlweg (1938) reported it to be 15 to 20 times as powerful as alpha oestradiol when both are administered by mouth. Harding (1944) found it at least 15 to 30 times, and Soule (1942) 50 to 70 times, as active as alpha oestradiol. Allen (1944) estimated it to be 26 times as active as hexoestrol. Soule (1943) said it is 5 to 20 times as powerful as stilboestrol but Harding (1944), like Allen (1944), puts this figure at 5 or 6. Most of these estimates appear to be based on its capacity for relieving menopausal symptoms, but Bickers (1946) concluded that in the treatment of anovular uterine haemorrhage 0.3 mg of ethinyl oestradiol is equivalent to 5 mg of stilboestrol.

When advance supplies of ethinyl oestradiol were put at our disposal\* it was decided to undertake a clinical trial, partly to confirm its value as an oestrogenic agent but mainly to assess its potency. For this purpose inhibition or suppression of lactation was chosen as the test object as it seemed preferable to the relief of climacteric manifestations, where the interplay of psychogenic factors makes the assessment of results difficult. An attempt was made to compare the potency of ethinyl oestradiol and stilboestrol, both being administered orally, and to determine within practical limits the minimal dose of each which is required to inhibit lactation. This latter is extremely difficult, if not impossible, to do with any degree of accuracy, because it varies with the spacing of doses and the number of days over which it is administered and the susceptibility of individual patients. For the purpose of this investigation the usual procedure consisted in starting treatment within twenty-four hours of delivery and in giving gradually decreasing amounts of oestrogen over the course of seven days. In a few of the later cases the duration of treatment was reduced. With a few exceptions the patients were observed for ten to fourteen days only, so any very late relapse will not have been recorded unless it was specially reported by the patient. No other treatment such as saline aperients and restriction of fluid intake was given. The results are classified into

Excellent—No sign of breast activity at all

Good—Not more than slight secretion or slight fullness of the breasts for one or two days. No discomfort

Fair—Moderate secretion or fullness without gross engorgement and insufficient to cause the patient more than minimal discomfort

Poor—Varying degrees of engorgement or free secretion of milk, sometimes necessitating a further course of oestrogen therapy

This type of assessment is similar to but not identical with the one used by Birnberg and others (1947)

### Trials with Ethinyl Oestradiol

Ethinyl oestradiol is supplied in tablets, each containing 0.05 mg active substance, for oral administration. The schemes of dosage employed and the results are set out below. Treatment was started within twenty-four hours of delivery, except when otherwise stated.

*Scheme 1—Technique* 5 tablets b.d. first day, 4 b.d. second day, 3 b.d. third day, 2 b.d. fourth day, 1 b.d. on each of the fifth, sixth and seventh days of treatment, total 34 tablets

\*We are indebted to Dr. W. J. Tindall of Organon Laboratories for a liberal supply of ethinyl oestradiol.

(1.7 mg) **Results** Eleven patients treated, ten did not have any sign of breast activity, while the other one noticed slight secretion on the tenth day (10 excellent, 1 good)

**Scheme II—Technique** 4 tablets b d first day, 3 b d second day 2 b d third day, 1 b d on the fourth, fifth, sixth, and seventh days of treatment, total, 26 tablets (1.3 mg) **Results** Eleven patients treated, nine with excellent result, the tenth had a little fullness and minimal discomfort in the breasts on the fifth day, while the remaining one, a girl of 14, had no breast activity whilst in hospital but is reported to have developed severe pain in the breasts on the fourteenth day, the condition developing into a breast abscess which had to be drained. Not having seen the patient at the time, we are unable to say whether she suffered engorgement of the breasts or whether the condition was an acute mastitis from the time of onset of the symptoms. This case is recorded, however, as showing a poor result (9 excellent 1 good, 1 poor)

**Scheme III—Technique** 2 tablets b d first and second days, 1 tablet b d third and fourth days, 1 tablet daily on the fifth, sixth, and seventh days of treatment, total, 15 tablets (0.75 mg) **Results** (a) Eight cases, excellent result in all (b) A second group of seven patients whose babies died after birth were treated by this technique starting later than the first day after delivery, often when lactation was already established. The results in this series were as follows

Case	Treatment Started	Result
1	4th day of puerperium	Excellent
2	5th	
3	3rd	
4	2nd	
5	3rd	Poor
6	3rd	Excellent
7	3rd	

**Scheme IV—Technique** 1 tablet b d for first four days, and 1 tablet daily on the fifth, sixth, and seventh days of treatment, total, 11 tablets (0.55 mg) **Results** Nineteen patients treated. Excellent result in 14 cases (4 patients not observed personally after the fourth day), good result in 2 cases (1 patient not observed personally after the seventh day), fair result in 2 cases, poor result in 1 case

**Scheme V—Technique** 1 tablet b d for four days, total, 8 tablets (0.4 mg) **Results** Two patients treated, both with excellent result

**Scheme VI—Technique** 2 tablets b d on first and third days only, total, 8 tablets (0.4 mg) **Results** Two patients treated, one excellent and one fair result

**Scheme VII—Technique** 1 tablet daily for four days, total 4 tablets (0.2 mg) **Results** Three patients treated, two good and one fair result

**Scheme VIII—Technique** 1 tablet daily on first and third days only, total 4 tablets (0.2 mg) **Results** Three patients treated, one good and two poor results

From our observations on the treatment of the whole series of 66 patients it is clear that ethinyl oestradiol, as judged by its ability to inhibit or suppress lactation, is an extremely powerful oestrogen. If it is administered orally in divided doses, in gradually decreasing amounts, over the course of seven days, a total of 0.75 to 1.3 mg is sufficient to ensure good results in a high proportion of cases, if not all. A total of 1.7 mg produces consistently good results and is probably an unnecessarily high dose. The response was excellent or good in 29 out of 30 women who received 0.75 mg or more and when the treatment was begun within twenty-four hours of delivery. Nevertheless, judging by the general experience with other oestrogens, it is almost certain that if the number of patients had been larger there would have been included a few who were less susceptible and an occasional poor result would have been recorded. When the dose is reduced to 0.55 mg a critical level is reached and the treatment may fail or be only partially successful in preventing breast activity. Even so, in a few patients as little as 0.2 mg appeared to be effective. So far as we can find the only other workers who have

published detailed results on the ability of ethinyl oestradiol to suppress lactation are Birnberg and others (1947). They gave 1.5 mg over the course of nine days and noted 74% excellent or good results, 16% fair results, and 10% failures among 145 cases.

### Trials with Stilboestrol

It is probably true to say that during the last ten years and in this country, stilboestrol has been the oestrogen most widely used for suppression of lactation. Various techniques are said to give good results. There is no need to review the literature in full, for this was done by Barnes (1942) and Prescott and Basden (1944). Some writers (Diddle, 1941; Gavioli, 1944) claim good results with a single dose of 5 or 10 mg on the first day, others have been disappointed with the results of giving 35 mg. Some give as much as 45 mg daily. There seems to be a wide variation not only in the response of individual patients but in the interpretation of results by different observers. Barnes (1942) gave a seven-day course of decreasing amounts of stilboestrol to 81 patients, the total dose being 30 mg in most cases, but more than this (up to 50 mg) in 22 cases. The treatment was not completely successful in 32, although in several of these cases there were signs of only minor breast activity. A repeat course of treatment was necessary in 20 patients in all, but these included only one of the 22 who received a maximum dose. This rather suggests that 30 mg is barely sufficient to ensure the optimum results, for which 40 to 50 mg is necessary. This conclusion is probably in keeping with the general experience for most clinicians, despite minor variations in technique, seem to give about this amount over four to ten days and are satisfied with the result. It is also borne out by other writers. Diddle, Nagyfy, and Sells (1942) obtained uniformly satisfactory results using 40 to 50 mg, but noted 4.5% failures when the total dose was between 25 and 35 mg and 40% failures with 10 to 20 mg. Coulton (1947), while controlling a series of cases treated with "meprane," gave stilboestrol to 73 patients and noted 40% failures when the total dose was between 10 and 20 mg, 4.5% failures when he gave 25 to 35 mg, and no failures with 40 to 50 mg.

For several years now we have as a routine given 41 mg over the course of eight days, the daily dose being 10, 10, 6, 5, 4, 3, 2, 1 mg, and the results on the whole have been good, although, in common with most observers, we have met occasional failures for which a further course of treatment has been necessary, and even that has sometimes failed. As part of this inquiry it was decided to determine the effects of stilboestrol given in smaller doses. The clinical work of the department is carried out in two hospitals. Ethinyl oestradiol was used for all patients in whom it was indicated in one hospital, and stilboestrol in the other. Both groups of patients were unselected, but the observers were not always the same. This latter disadvantage was counteracted as much as possible by having the details of all the results analysed by an independent worker. The details for the stilboestrol therapy are set out below, treatment being started within twenty-four hours of delivery in all cases.

**Scheme IX—Technique** Consecutive daily doses of 5, 4, 3, 2, 1, 1 mg, total, 17 mg. **Results** Twenty-two patients treated. Excellent result in 2 cases, good result in 6 cases, fair result in 6 cases, poor result in 8 cases (supplementary course of treatment given in four).

**Scheme X—Technique** Consecutive daily doses of 10, 10, 5, 4, 3, 2, 1 mg, total, 35 mg. **Results** Twelve patients treated. Excellent result in 2 cases, good result in 6 cases, fair result in 2 cases (both had a supplementary course of treatment although it was not strictly necessary), poor result in 2 cases (supplementary course of treatment given in both).

The second group is very small and the significance of the results is doubtful. The findings in both groups are, however, in keeping with those of other writers, and go to show that a total of 35 mg or less of stilboestrol is hardly enough to ensure consistently good results, while considerably smaller doses are quite unreliable in their effects.

#### Relative Potency of Ethinyl Oestradiol and Stilboestrol

So far as the suppression of lactation is concerned, and when both substances are given orally in divided doses for seven days, our findings in admittedly small groups of patients lead us to conclude that 0.55 mg of ethinyl oestradiol is rather more effective than 35 mg of stilboestrol. A total of 0.75 mg to 1.3 mg gives as good if not better results than we have obtained using 41 mg of stilboestrol as a routine during several years. As judged by its ability to suppress breast activity in the puerperium, ethinyl oestradiol, weight for weight, seems to be not less than 50, and it may be 70, times as potent as stilboestrol. This estimate is higher than that of other workers who based their conclusions on the treatment of menopausal symptoms. It is of course impossible to be exact in these matters because so many factors, such as the rate of absorption, inactivation, and excretion, enter the picture and may act to the advantage of one preparation when one condition is under treatment and to its disadvantage when put to another use. Stilboestrol, for instance, is utilized and excreted quite rapidly. Its fleeting action may be a disadvantage in the suppression of lactation and may explain why late relapse (i.e., breasts filling and secreting on the ninth or tenth day) is relatively common. Our impression is that cases treated with ethinyl oestradiol are less likely to suffer these late relapses, although they do occur. In this respect the suggestion quoted by Lyon (1944) that ethinyl oestradiol is absorbed and utilized comparatively slowly may be significant. Nevertheless this idea is not supported in any strong degree by Lyon's observation to the effect that menopausal symptoms recurred within one to twelve days (average 5.5 days) of suspending treatment. It was the possibility of ethinyl oestradiol having a prolonged action which prompted the treatment of a few cases by Schemes V, VI, VII, and VIII. The results, however, are inconclusive, and further tests with a few doses widely spaced are being carried out.

It was pointed out earlier that several workers have compared the potency of ethinyl oestradiol with that of alpha oestradiol and have variously estimated it to be 15 to 70 times greater. We have no experience of alpha oestradiol, but Diddle and others (1942) reported that for the purpose of suppressing lactation stilboestrol by mouth and alpha oestradiol in propylene glycol administered sublingually are about equal in effectiveness provided the latter is given at regular and short intervals. If this is so then the comparisons made between ethinyl oestradiol and alpha oestradiol can perhaps be taken to give an approximate indication of the relative potencies of ethinyl oestradiol and stilboestrol.

#### Toxic Effects of Ethinyl Oestradiol

All writers note that ethinyl oestradiol like most oestrogens and particularly the synthetic ones, is apt to produce various symptoms in non-pregnant women. These include nausea, vomiting, headache and malaise, dizziness, and drowsiness. Such symptoms are common and occur in about 10 to 15% of cases when the daily dose is 0.1 to 0.15 mg, and in 20 to 25% when doses of the order of 0.2 mg daily are given (Harding 1944; Lyon, 1944; Birnberg 1947). Reduction of the dose results in disappearance of the toxic manifestations. It would appear that most non-pregnant women can take 0.05 mg a day without ill

effect, although even this small dose may cause nausea and vomiting in some (Birnberg, 1947). These observations are of interest because it has often been stated that it is the synthetic oestrogens which produce vomiting and that the natural ones do not. Ethinyl oestradiol is a derivative of the naturally occurring oestradiol, and yet is as liable as if not more liable than, synthetic oestrogens to cause nausea and vomiting. They rather favour the view which has long been taken by some workers, that the toxicity of any preparation, natural or synthetic, is dependent on its oestrogenic activity rather than its chemical structure. In our clinical trial no ill effects of any kind were noted\*. This is not surprising, because pregnant or recently pregnant women rarely show toxic reactions even when given massive doses of any form of oestrogen. Thus it is well known that as much as 1,000 to 2,000 mg of stilboestrol can be given within four to seven days without upsetting a puerperal woman. We have confirmed this to the extent of giving 700 mg in seven days to three patients.

Now that ethinyl oestradiol is becoming freely available in this country it is perhaps relevant to point out that, like other oestrogens, it may have other undesirable side-effects, and the likelihood of these again reflects its high potency. For instance, even in moderate doses it can cause endometrial proliferation to the state of hyperplasia (Wiesbader and Filler, 1946; Birnberg and others, 1947), with resulting heavy uterine losses and a disturbed menstrual cycle (Harding, 1944). Soule (1943) reported that as little as 0.85 mg given in divided doses can cause uterine haemorrhage in a post-menopausal woman, and Birnberg and others (1947) noted that 20% of women given 0.05 to 0.15 mg daily for climacteric symptoms developed post-menopausal haemorrhage. In women who are still menstruating 0.05 mg daily sometimes delays the onset of menstruation or makes the menstrual flow excessive (Lyon, 1944). Also, like other potent oestrogens, ethinyl oestradiol is liable to cause swollen and painful breasts and to lead to deep pigmentation of the nipple and areola. If, therefore, its use becomes widespread—and it is likely to, for the drug is cheap and efficient and can be given by the oral route—the fact that it is extremely potent should be recognized, otherwise it will almost certainly be the cause of many cases of post-menopausal haemorrhage in older women and menstrual disturbances in younger ones. Since 0.05 mg is equivalent to not less than 1 mg of stilboestrol and may well be equal to 2 or 3 mg, it is probably too powerful a preparation to use for the relief of climacteric symptoms. The introduction of tablets of weaker strength might obviate this difficulty.

#### Summary

An account is given of a clinical trial of ethinyl oestradiol—an oestrogen new to this country.

Its ability to suppress lactation in a series of 66 patients is assessed and compared with that of stilboestrol. The results go to show that ethinyl oestradiol is most efficient in preventing activity of the breasts.

A total dose of 0.75 to 1.3 mg spread over seven days gave good results in 21 out of 22 cases. When the total dose was reduced to 0.55 mg the results were less satisfactory but rather better than those obtained with 35 mg of stilboestrol. Since it takes 40 to 50 mg of stilboestrol to produce good results in a high proportion of cases it is reckoned that ethinyl oestradiol is at least fifty times more active than stilboestrol for the purpose of suppressing lactation.

There is evidence in the literature that it is equally potent in producing other oestrogenic effects, thus when it comes

\*Since completing this series of cases we have seen one puerperal woman develop an urticarial rash twenty-four hours after taking 0.55 mg of ethinyl oestradiol within the space of twelve hours. The rash may or may not have been caused by the drug.

into general use there will be need for caution over dosage, otherwise ill effects such as menstrual disturbances, endometrial hyperplasia, and postmenopausal bleeding, as well as toxic reactions such as nausea and vomiting will be commonly seen

We are grateful to the other members of the medical staff of the Liverpool Maternity Hospital and Mill Road Infirmary for allowing us to carry out this trial on their cases

## MÉNIÈRE'S SYNDROME

## SUCCESSFUL TREATMENT BY SURGERY ON THE SYMPATHETIC

BY

E R GARNETT PASSE, FRCS

Surgeon Ear Nose and Throat Department, King Edward Memorial Hospital Ealing

AND

J S SEYMOUR, MB, BS

Ménière first described his syndrome in 1861, but had inadequate knowledge of the underlying aetiology. He reported a case of a patient who died after an acute illness of five days, and described the necropsy findings, it would seem that acute haemorrhagic labyrinthitis was the cause of the syndrome

By definition Ménière's syndrome is a malady characterized by attacks of rotational vertigo accompanied by a tendency to fall, occurring at irregular intervals and associated with tinnitus and progressive nerve deafness. The attacks are sudden in onset and may occur without warning, and if severe the patient may fall to the ground with great violence. Commonly there is an associated vomiting, which may be of varying severity, sometimes lasting for hours to the point of exhaustion. Accompanying these vestibular disturbances are degrees of cochlear involvement the symptoms of which are tinnitus and nerve deafness. At first the nerve deafness is mild and occurs only with the attacks, but in the later stages of the syndrome it becomes progressively worse and is manifest permanently between the attacks, until finally it is complete on the side affected

In the earlier stages the patient is free from giddiness between the attacks, but with progression of the syndrome

there is a constant state of dizziness, which is considerably accentuated by any sudden movement of the head

The tinnitus is variable in type and severity, it may be a pulsating throbbing variety or a high-pitched constant note either singing or hissing in character. There is no known precipitating factor, and the absence of premonitory signs makes the attacks the more distressing, the patient developing a constant dread of the next occurrence, thus a not inconsiderable functional element quite often exists with the syndrome—a fact recorded by Levi, O'Leary, and Furstenberg—and great care has to be paid to detail in the examination in order to determine the degrees of organic and functional symptoms

## Aetiology

Much confusion exists about the exact aetiology of Ménière's syndrome, as evidenced by the considerable volume of literature on the subject and the extreme diversity of views expressed—some substantiated by necropsy findings and pathological investigations, some based purely on clinical observation and empirical therapy, and others founded very largely on assumption. Attributable factors in the literature cover such a wide field as poisoning from lead, mercury, arsenic in alcohol, drugs such as salicylates, circulatory disturbances of hypertension, arteriosclerosis, anaemia, the exanthemata, the chronic infections, syphilis and tuberculosis, virus infections, chronic diseases such as leukaemia, purpura, and pernicious anaemia, tumours of the cerebello-pontine angle, and trauma

Causative theories are equally diverse, ranging from disturbance of sodium metabolism in the local tissues (Furstenberg) to vascular disturbances. The latter Miles Atkinson describes as the "mechanics" of Ménière's syndrome, and the patients are divided into two groups determined by an intradermal histamine test—a vasoconstrictor group and a vasodilator group, in the ratio of five to one. He then treats them accordingly with nicotinic acid or histamine

Hallpike and Cairns noted at necropsy a distension of the endolymphatic system, with degenerative changes in the organ

## Anatomical Consideration

The blood supply of the inner ear is derived from two sources. The first, of major significance, is the internal auditory artery, which, as is common knowledge, is a branch of the anterior inferior cerebellar artery, or, less commonly, it may arise direct from the lower part of the basilar artery. This in turn is formed by the union of the vertebral arteries at the base of the skull

The subsequent course of the internal auditory artery is through the internal auditory meatus, accompanying the auditory and facial nerves to its distribution near the inner ear. This distribution would seem to take various forms according to Nabeya, ranging from an almost equal dichotomous division into cochlear and vestibular arteries to a predominant cochlear artery with smaller branches to the vestibule and vice versa, or a vestibular artery dividing to send branches to both cochlear and vestibule. Siebenmann describes the blood supply as a more or less equal division of the internal auditory artery to both cochlear and vestibular fields of distribution. It would seem that the variability of the distribution of the arteries indicated by Nabeya might well account for the variable degree of association of cochlear and vestibular signs in Ménière's syndrome-complex. This would reasonably fit in with the view held by us that the predominant aetiological factor is one of vasoconstriction, and that the smaller vascular distribution to a particular portion of the organ will imbue

that artery, by virtue of its size, with greater vasoconstrictor properties—hence a preponderance of symptomatology of the organ of distribution

The second source of blood supply to the inner ear arises from vessels of the middle ear. This is said, however, to be a somewhat rare source, and need hardly be considered as presenting a possible fallacy in the rationale of treatment.

Bergglas found around such vessels as the iliac arteries large nerve strands at the union of the adventitial and muscular coats. He believed that this plexus extended throughout the muscular tree and was everywhere continuous.

H. H. Woollard states that vascular tone from the aorta to the periphery is maintained by vasomotor nerves in two ways. First, in the aorta large bundles from adjacent sympathetic ganglia composed almost entirely of non-medullated nerve fibres pass into the adventitia, some lying superficial and some deep near the media. The bundles continue to the periphery, forming a plexus of non-medullated fibres from which further fibres pass inwards and form an abundant mesh of the finest fibres within the muscle coat. Secondly, from the peripheral nerves these fibres are almost entirely medullated. The muscular coat is innervated by the fine network, the individual elements of which divide and fuse together to give absolute continuity complete throughout the vascular wall. Physiologically, Langley, Bayliss, and Gaskell have shown that bars of constrictor fibres are exclusively sympathetic ganglionic and that there is no other source of supply.

Hence destruction of the cell station in the stellate ganglion and blocking of the post-ganglionic pathways to the auditory vessels would presumably deal with the problem if the vasoconstriction is of central origin, for it is yet to be seen whether sensitization of sympathetic nerve endings to adrenaline or adrenaline-like bodies occurs in the terminal branches of the internal auditory artery after removal of the stellate ganglion. This destruction is undertaken by ganglionectomy and stripping and cutting the vertebral artery. It was felt that cutting the artery was necessary because of the possibility of impulses being conveyed through the intramural plexuses, a number of which exist, as shown by H. H. Woollard, at varying depths in the arterial wall. Also Leriche's periarterial sympathectomies never proved effective, the spasm returning to the vessels from days to weeks after the operation, hence indicating the probable existence of alternative pathways. Woollard showed that the nerve supply of arteries came from two sources—the one from periarterial fibres, and the other from neighbouring nerves. The fibres from neighbouring nerves were myelinated and probably not of vasoconstrictor function, so that the failure of Leriche's operation would seem to be due to the establishment of the pathway again probably through the arterial wall itself.

That after ganglionectomy and cutting of the artery there is the possibility of sympathetic impulses reaching the vessel from the opposite vertebral artery via the circle of Willis or alternatively from the component of Oort of the eighth nerve has not been overlooked but to the best of our knowledge no evidence in support of these sources is known. It is conceivable that primary nerve deafness may also be due to vasoconstriction since the deafness is part of the syndrome the possibility in these cases being that the effect of the spasm is felt by the artery of supply to the eighth nerve with subsequent permanent damage. It was with this in view that a few cases of early pure nerve deafness were selected for operation and research in this field is being continued.

In the absence of definite pathological evidence it would seem that vasoconstriction plays a predominant part in the production of the syndrome. Siebermann points out that

the internal auditory artery which supplies the labyrinth may be readily influenced by excitation of the vasoconstrictors on account of the narrowness of the artery relative to the basilar artery. Its state of contraction depends upon the nerve plexus surrounding the vertebral artery and its branches coming from the thoracic part of the sympathetic cord and inferior cervical ganglion. It was with this in view that a means to prevent the flow of impulses through the plexus was attempted.

### The Operation

Under intratracheal gas-oxygen with positive pressure the anterior approach is favoured, with the patient in a supine position and the head extended and rotated to the opposite side. This serves to bring the transverse process of the seventh cervical vertebra into prominence. Through a 2-in (5-cm) slightly curved incision dissection of the subclavian triangle is carried out down to the deep fascia of the neck. The clavicular head of the sternocleidomastoid muscle is divided  $\frac{1}{2}$  in (1.25 cm) above its clavicular origin. The phrenic nerve is then isolated and retracted out of the way. The scalenus muscle is divided and the second part of the subclavian artery is then seen. Careful dissection brings into view the thyroid axis, and if the dissection is carried anteriorly the vertebral artery is exposed. It is sometimes a help to divide the inferior thyroid artery between ligatures. When this is done the vertebral artery becomes more accessible, and its adventitious coat may then be stripped from the origin of the artery until it enters the foramen in the transverse process of the sixth cervical vertebra. This artery is larger than one might expect, often being twice the diameter of the inferior thyroid artery. It arises from the upper and back portion of the subclavian artery, and its exposure may be facilitated by retracting the subclavian artery downwards and forwards. In the areolar tissues surrounding the artery may be found sympathetic branches from the stellate ganglion, which it crosses. The vertebral artery is freed and then divided between ligatures. Careful dissection is made through Sibson's fascia, and the parietal pleura is stripped downwards as far as the transverse process of the second thoracic vertebra. This brings into view the pre-ganglionic fibres of T1 and T2 as they ascend to blend with the inferior cervical ganglion to form the stellate ganglion, the variations and branches of which are notorious. This ganglion is freed from its surrounding loose fatty areolar tissue and excised after dividing the pre-ganglionic fibres of T1 and T2. Several small veins in this tissue may sometimes cause temporary and troublesome oozing if torn. The wound is then closed in layers. Only six days' stay in hospital is necessary.

### Immediate Result of the Operation

Horner's syndrome is of course apparent at once. The contracted pupil and ptosis of the upper eyelid rarely worry the patient after the first few days and tend to correct themselves during the first few months. However, should the ptosis persist a small plastic operation is all that is required to raise it. The dryness of the hand does not cause discomfort.

**Ear**—Patients state that the head feels clearer and that they no longer have the sense of uneasiness or feeling of pressure in and around the ear that Meniere's syndrome produces and the ear loses its stuffed-up feeling. The effect on the tinnitus is varied. In Cases 4, 5, and 9 it was completely relieved, in six cases it was partly alleviated, while in the remaining three it was unaltered. The hearing shows immediate improvement, which has been maintained for the time those cases have been under observation.

It is well known that Meniere's syndrome often affects one ear after the other. We have not yet had the

condition occur in the ear of the unoperated side, but, if it should, then there is no valid reason why the stellate ganglion of that side should not be removed, together with stripping and possible ligation of the vertebral artery, though the safety of this latter procedure should first be proved by animal experimentation. This mode of treatment has been so effective that it suggests the possibility of successfully alleviating an acute attack of Menière's disease by means of a "novocain" block of the stellate ganglion—a relatively simple procedure.

**Nose**—Some dryness of the mucosa is observed, but this is not maintained for more than a few weeks.

**Throat**—Nothing observed.

Taste and smell remain unaltered, and there is no appreciable effect on salivation.

**Complications**—The disturbance of circulation through the vertebral artery might conceivably give rise to thrombosis of the post-inferior cerebellar artery in arteriosclerosis. This would then result in degenerative changes in the dorso-lateral area of the medulla, probably involving the dorsal and ventral spinocerebellar tracts, the spinal tract and nucleus of V, the lateral spinothalamic tract and nucleus ambiguus, and even the vestibular nerve. However, since the original syndrome may be caused by the arteriosclerosis, operation is not undertaken in these cases, and therefore the complication is hardly likely to occur.

### Case Reports

Reports of twelve cases operated on during the last twelve months are given. The routine clinical examinations, including caloric tests and inflation of eustachian tubes, were carried out. Caloric tests showed normal variations that are encountered with labyrinthine dysfunction due to Menière's syndrome. In all cases the eustachian tubes were patent. Audiometric examination was made of all ears, and records of both air and bone conduction were taken, but for the sake of brevity only air-conduction records are published. Wherever the air conduction was improved there was a corresponding improvement in the bone conduction.

**Case 1**—A married woman aged 46 had had severe attacks of giddiness for seven months—she fell four times in one week. Attacks occurred every two or three days, starting with great roaring in the left ear and completely prostrating her for 24 to 48 hours. Severe deafness and tinnitus involved both ears. There was no great improvement on salt free diet and sedation for three months. There was a history of previous middle-ear disease (right ear) but this had now cleared up.

On July 1, 1947, left stiellectomy with division of pre-ganglionic fibres of T1 and T2 and division of fibres going to vertebral artery was carried out. There was immediate relief of vertigo and tinnitus (pulsating tinnitus completely relieved) though an occasional high-pitched note was present. Hearing was greatly improved for both air and bone conduction.

Cycles per Second		138	256	512	1 024	2 048	4 096
Loss in decibels	Pre-op June 1 1948	60 45	70 45	90 60	90 70	100 65	— 80

**Case 2**—A man aged 25 had a sudden onset of vertigo in December, 1946 accompanied by severe tinnitus in the right ear and vomiting and was confined to bed for three weeks. Further attacks from January to March, 1947 were accompanied by increasing deafness. He was then free until June, when attacks restarted. Tinnitus had persisted since the first attack and was of the continuous type. In June, 1947 he was given a salt-free diet with sedation, restricted fluids, and injection of calcium. No improvement resulted in either giddiness or tinnitus. He had also had migraine since boyhood.

Operation (July 1 1947) right stiellectomy and stripping of vertebral artery. Result—except for a slight attack of giddiness

on Sept 2, accompanied by tinnitus in the left ear, there has been no further attack, the hearing has very much improved and the tinnitus, while still present, has greatly lessened, and he has had no further attack of migraine to date.

Cycles per Second		128	256	512	1 024	2 048	4 096
Loss in decibels	Pre-op June 7 1948	55 30	60 30	65 25	55 20	75 45	— 65

It is highly probable that the slight attack on Sept 2 was due to Menière's syndrome affecting the other ear.

**Case 3**—A woman aged 21 underwent a fenestration operation for clinical otosclerosis (by E.R.G.P.) on the left ear on Aug 20, 1946, with a satisfactory result. On June 16, 1947, she began to complain of an increase in the tinnitus of the right ear, accompanied by severe attacks of vertigo and vomiting. It was decided that the fenestrated ear was not responsible for the syndrome. Cocainization of the sphenopalatine ganglion on the right side completely relieved the tinnitus for several hours.

Right stiellectomy was performed on Aug 14, and next day the head was clear and the noises had ceased. Up to May 29 1948 no further attacks of giddiness had occurred, but slight tinnitus of a continuous character had returned. The tinnitus could be stopped by biting hard on a piece of cork between the right upper and lower molars. The hearing has decidedly improved.

Cycles per Second		128	256	512	1 024	2 048	4 096
Loss in decibels	Pre op June 8 1948	35 20	30 20	40 25	35 15	45 35	55 50

**Case 4**—A woman aged 32 had for 10 years had increasing deafness of nerve type, associated with severe tinnitus and bouts of vertigo, the latter symptom being present during the past three years and increasing in frequency and severity. Right stiellectomy was performed on Aug 15, 1947. Up to June 16, 1948 no further attack of vertigo had occurred and there was complete cessation of tinnitus and great improvement of hearing.

Cycles per Second		128	256	512	1 024	2 048	4 096
Loss in decibels	Pre op Post op	45 35	40 35	55 40	60 40	45 20	40 30

**Case 5**—A man aged 65 had his left ear first affected in 1946, he had severe giddiness, vomiting, tinnitus and increasing deafness with each attack. In 1947 the right ear started to be involved, with severe prostrating attacks. Tinnitus of continuous and pulsating types was present for 21 months. There had been no previous middle ear disease.

On Aug 29, 1947, right stiellectomy with division of pre-ganglionic fibres of T1 and T2 and sympathetic nerves going to vertebral artery, was carried out. On Sept 1 there was no giddiness, no tinnitus in right ear and the head felt clear. On March 31, 1948, the giddiness and tinnitus had gone and the hearing was greatly improved for both air and bone conduction.

Cycles per Second		128	256	512	1 024	2 048	4 096
Loss in decibels	Pre-op June 14 1948	35 30	35 20	35 10	40 20	40 40	70 75

**Case 6**—A male fitter aged 48 had a history of 2½ years severe prostrating attacks of vertigo accompanied by vomiting, deafness and tinnitus in the left ear. Tinnitus was of a continuous roaring nature. On Jan 8, 1948, left sided stiellectomy was performed with stripping of the vertebral artery. On April 22 there was no giddiness, the tinnitus was unaltered but hearing had somewhat improved.

Cycles per Second		128	256	512	1 024	2 048	4 096
Loss in decibels	Pre-op June 12 1948	40 25	50 35	60 45	65 40	50 35	45 45

**Case 7**—Two years ago a man aged 71 began to have severe attacks of giddiness which, despite all conservative treatment

including nicotine acid, continued until he was unwilling to leave the house. Hearing steadily deteriorated in the right ear, and was accompanied by a continuous high pitched tinnitus, which became worse before an attack. In childhood the patient had had a suppurative otitis media.

On Feb 2 1947, right-sided stelleotomy was carried out. By Jan 24 1948 the attacks had lessened, and he could walk even during an occasional mild feeling of unsteadiness. On Feb 9 the noises were unaltered but no attacks of giddiness now occurred. On May 3 he was playing golf for the first time since the onset of vertigo and now drives his car without any apprehension.

June 11 1948	35	45	50	55	55	75

This case shows gradual improvement of the high frequencies.

**Case 8**—A woman aged 53 had a history of shingles on the left side of the face accompanied by severe attacks of giddiness, which came on usually while she was sitting quietly and was aggravated by stooping. Nerve deafness was present in the left ear. There was tinnitus both pulsating and continuous.

On Feb 5, 1948, left stelleotomy was done, with stripping of the vertebral artery. On March 2 there was no further vertigo, the head felt clearer and the left side of the nose, which was always blocked especially at night was free. This nasal obstruction was not complained of before the operation, and unfortunately no particular note was made of the condition of the nasal mucosa on the left side though now it appears less congested than the right side. The tinnitus is unaltered.

Cycles per Second	128	256	512	1024	2048	4096
Loss in decibels						
Pre-op	20	25	35	35	45	60
May 22 1948	25	25	30	20	25	50

**Case 9**—Six years ago this patient, a woman aged 41 had vertigo on and off for one year with increasing deafness of the left ear associated with a continuous low buzzing sound. Two years ago vertigo restarted with deafness and tinnitus in the right ear. Rest, salt free diet, and sedation brought about considerable improvement in the vertigo, deafness, and tinnitus, but symptoms recurred immediately this treatment was stopped. It was considered advisable to try to save the remaining hearing in the right ear so sympathectomy was decided upon.

On March 15 1948 right stelleotomy was performed with division of the pre ganglionic fibres of T1 and T2 and stripping and ligation of the vertebral artery. There was an immediate cessation of vertigo and a clearer feeling in the head. Tinnitus had ceased and a great improvement had occurred in air and bone conduction.

Sept 21 1948. This patient had a recurrence of her vertigo and unsteadiness accompanied by tinnitus and deafness. The attack was very mild compared with her former attacks but nevertheless was a definite one.

Cycles per Second	128	256	512	1024	2048	4096

June 16 1948	10	20	10	15	15	25

**Case 10**—A woman aged 33 had an 18 months history of increasing nerve deafness and tinnitus in the right ear. She had had bouts of severe vertigo with nausea and vomiting which lessened the hearing worse than before. Right-sided deep mucoid pain of a shooting character. She had undergone conservative treatment together with repeated eustachian inflation. For a period of five weeks no seas were noticed. The patient felt more comfortable and the tinnitus in the right ear had lessened.

Cycles per Second	128	256	512	1024	2048	4096
Loss in decibels						
Pre-op	25	35	45	55	55	75
June 14 1948	25	35	45	55	55	75

On April 31, 1948 right stelleotomy with division of the vertebral artery was performed. When examined on June 14 there was no further giddiness, and she said her head felt clearer than it had since deafness began. Hearing had improved but the tinnitus had only slightly lessened.

**Case 11**—This patient, a woman aged 63, gave a history of sudden onset of very severe attacks of vertigo accompanied by deafness and tinnitus during the past 16 months. The tinnitus was like faintly escaping steam, and the deafness had been much worse during the last four weeks. She was very apprehensive of further attacks. Sedation and calcium tried over a three-months period gave no relief.

Right stelleotomy and ligation of vertebral artery were carried out on May 17, 1948, and by June 14 there was no giddiness whatsoever. She then led a normal active life and did her household work. The head felt clearer but she complained of slight pain and weakness of the right forearm. This was rapidly lessening. Tinnitus was still present, but was decreasing. The hearing had not appreciably altered.

**Case 12**—In 1934 this patient, aged 38 had her first attack of giddiness with tinnitus in the left ear. She was free of further attacks until 1946, but they had been present on and off ever since. When attacks were severe they were accompanied by vomiting and an increase in the tinnitus in the right ear. The hearing of the left ear had remained practically stationary since 1934, but that of the right ear steadily decreased with each subsequent attack. As she had a history of three miscarriages a Wassermann test was done and this proved negative. The tinnitus was worse at the beginning of an attack and faded off altogether for a few hours after the vomiting had ceased. The noises were relieved to a soft murmur by cocainization of the sphenopalatine ganglion of the right side.

On May 14 1948 right stelleotomy with division of vertebral artery was performed. On June 12 there was no giddiness, the tinnitus had lessened, but the deafness had not yet improved.

Pathological examination of the stellate ganglion was carried out in all cases, but no abnormality was discovered in any of them. This finding may be compared with that of J W Budd (quoted by Mogan and Baumgartner, 1945), who demonstrated definite pathological changes in the superior cervical ganglion in a case of Ménière's disease, as did J W Kernohan, of the Mayo Clinic. Details of the results are given in the accompanying table.

Details of Results

Case No	Stellate Ganglion	Vertebral Artery	Vertigo	Tinnitus	Hearing
1	Excised	—	Relieved	Lessened	Improved
2		Stripped			
3		—			
4		—		Relieved	
5		—			
6		Stripped		Unaltered	
7		—			
8		—		Relieved	
9		Stripped and ligated			
10				Lessened	Stationary

### Summary and Conclusions

A series of 12 cases of Ménière's syndrome which failed to respond to conservative treatment were subjected by one of us (E R G P) to stelleotomy and division of the pre ganglionic fibres of thoracic 1 and 2. In two cases the vertebral artery was stripped while in four cases it was either ligated or divided after the adventitious coat had been removed. The reason for the latter process is given in the context. In each case the vertigo attributable to that ear has been completely relieved except in Case 9.

Whether the recurrence of vertigo in this case was due to hypersensitivity to adrenaline or adrenaline like bodies following excision of the ganglion (for the patient was hard at work again and under considerable mental strain) or whether some sympathetic fibres to the ear may also originate on the opposite side to a greater or lesser extent in individual cases is not known but the fact that there has been a marked improvement on the administration of ergotamine would suggest that the former view is the more likely of the two, in which case division of the pre ganglionic fibres together with stripping and ligation or division of the vertebral artery would be the operation of choice. This has now been done in more recent cases with the same beneficial result on the vertigo, added to which it has the advantage of avoiding a Horner's syndrome.

The result upon the tinnitus is apparently unpredictable, though on the whole it was reduced—in three cases it was completely relieved. The relief seems to be more pronounced with the pulsating type of tinnitus than with the continuous variety. Each patient suffered from concomitant nerve deafness and in all except the last two most recent cases there has been improvement (in some ears very markedly) of hearing by both air and bone conduction. If the nerve deafness is very severe it is beyond relief.

It is felt that further work along these lines will greatly aid in elucidating the aetiology and pathology of this distressing complaint and its accompanying tinnitus and nerve deafness.

It is interesting to record that a further series of stellec-tomies has been performed for tinnitus alone (to be published later), but we forbear to make further comment on the role of the sympathetic on tinnitus at this stage.

In the meantime a new surgical method of treating Ménière's syndrome, having tremendous advantages over the old surgical destruction of the internal ear is at our disposal.

For the last two years 45 severely disabled men have been happily and gainfully employed at Haven Products, Ltd, a 'sheltered workshop' on Clydeside. They work a regular 8 hour day five days a week and are paid a basic wage of 2s 1½d an hour plus bonuses. The Nuffield Provincial Hospitals Trust has recently published an illustrated pamphlet describing the development of the workshop and the work done there. The men manufacture electro-thermic quilts, and the machines are adapted to suit the needs of individual workers. Doors are made specially wide to allow invalid chairs to pass through. Invalids have railings fitted so that men who must use their hands to get about may be helped, and transport is organized from the workers' homes. Four travel to the workshop in motor-chairs and fifteen require ambulance transport. A medical advisory committee, consisting of consultants from the three large voluntary hospitals in Glasgow, a senior medical officer of the Ministry of Pensions, three almoners, and an observer from the Ministry of Labour, was set up to advise on the planning and equipment of the factory, to help in the selection of suitable disabled men, and to ensure that the men's disabilities were not aggravated by their work. The men are medically examined every year, but medical supervision is kept in the background so far as possible. The venture has been very successful both financially and as an experiment in the restoration of the men's self-confidence and contentment. Harmonious relationships prevail in the workshop, and the report emphasizes particularly the enthusiasm and the sense of corporate life enjoyed by the men. Copies may be obtained from the Nuffield Provincial Hospitals Trust, 12 and 13 Mecklenburgh Square, London W C 1 and 10 Duke Street, Edinburgh.

## "RHEUMATOID DISEASE" WITH JOINT AND PULMONARY MANIFESTATIONS

BY

PHILIP ELLMAN, MD, FRCP

AND

R E BALL, MB

(From the Rheumatism Unit, St Stephen's Hospital, London)

It will be generally accepted that rheumatoid arthritis, like pulmonary tuberculosis, is a systemic disease with local manifestations, the former in the joints, the latter in the lungs. Moreover, its systemic nature may be manifested, as recent studies have shown, by widespread pathological changes in various tissues and organs.

Our own studies, confirming those of other observers (see Hench *et al*, 1948), have shown that in certain cases the bones may exhibit atrophy and even widespread cystic changes, and the peripheral nerves may become involved, with resultant neuritic pains, paraesthesiae, and trophic changes. Biopsy studies of the muscles may reveal microscopic alterations in the form of perivascular lymphocytic infiltration and macrophages in the perimysium and endomysium akin to those sometimes seen in periarthritis nodosa and disseminated lupus. Cardiac lesions may also occur almost identical with those following rheumatic fever, while other accompanying lesions may be found in the spleen, liver, lymph glands, subcutaneous nodules, pleura, and even in the eye in the form of iritis and scleritis. In one recent case there was good reason for regarding a kidney lesion (Ellis type 2) as part of the rheumatoid process.

The purpose of this paper is to report three cases in which an accompanying pulmonary lesion appeared as an integral part of the "rheumatoid state". A careful search of the literature has not disclosed any earlier records.

## Case 1

A fitter's mate aged 47 was admitted under the care of one of us (P E) to the Rheumatism Unit and later to the Leatherhead Emergency Hospital, and when first seen on Dec 14, 1945 gave the following history. Two and a half years previously, while he was in a fair state of general health, pain and stiffness started in the right knee joint. During the next few months the fingers, wrists, elbows, and left knee became involved. Swelling of the affected joints was present while active and subsided with rest. Until the time of admission he had had several courses of physiotherapy at different hospitals. He had lost 2 st (127 kg) in weight since the onset of the illness. There was a previous history of pleurisy progressing to empyema at 11 years of age and malaria at 21 and 24 years. There was no significant family history.

On examination he was pale and toxic and wasting involved subcutaneous tissues and muscles. Examination of the locomotor system revealed evidence of swelling of the proximal interphalangeal joints, wrists, elbows and knees and fibrous nodules were present over both olecranon processes, sacrum and scalp. Examination of the lungs showed poor air entry, and breath sounds diminished at both bases where numerous crepitant rales could be heard. The heart, abdomen and central nervous system were normal. Blood pressure 130/90.

Pathological investigations showed ESR 56 mm at first hour (Westergren), red cells 3,670,000, Hb 66%, C1, 0.83, white cells 8,000 (polymorphs 67%, lymphocytes 29%, monocytes 3%, eosinophils 1%). G.C.F.T. negative, serum uric acid 12 mg per 100 ml, Mantoux, weak positive. Repeated sputum examinations including concentration techniques were all negative for tubercle bacilli. General bacteriological examination of the sputum was not significant. Fluid aspirated from the left knee-joint was purulent and contained many polymorphs but was sterile on culture.

Radiological examination of the wrists, knees, and finger-joints showed osteoporosis, loss of joint space and erosions characteristic of the rheumatoid type of arthritis. There was evidence of a fine reticulation throughout both lung fields with a chronic bronchopneumonic lesion.

On March 26 1946 he began to complain of cough and produced small amounts of mucopurulent sputum. In April he developed a generalized purpura but the bleeding time was normal and platelets numbered 310 000 per cmm. His general condition gradually deteriorated and he became increasingly wasted until June 17 when he developed a pyrexia ranging about 99-100° F (37.2-37.8° C) became dyspnoeic and cyanosed, and coughed up much frothy sputum. These symptoms gradually increased in severity being unaffected by penicillin therapy until his death on June 23.

**Post mortem Examination** (performed by Dr D N Nabarro 18 hours after death)—The body was that of a middle aged poorly nourished man with polyarthritis. The dura mater was somewhat adherent over the surface of the brain which was

FIG. 1.—Case 1. Photomicrograph showing interstitial pneumonitis with well marked fibrosis between the lung alveoli. (x 100)

slightly congested but was otherwise normal. Respiratory system. There were fairly dense pleural adhesions, more especially marked over the lower lobes; no free fluid was seen. The trachea and bronchi contained mucopus. The lungs were firm throughout with nodular areas suggestive of a bronchopneumonia. Both lungs were congested and oedematous, and on section showed many areas of recent bronchopneumonia. However, the lungs as a whole were firmer than normal and suggested a chronic fibrosing pneumonitis. There was no evidence of tubercle or sarcoidosis. The mediastinal lymph nodes were enlarged and showed evidence of chronic inflammation. **Cardiovascular system.**—The pericardium contained a small amount of clear straw-coloured fluid. The heart was slightly enlarged and the myocardium was pale and fatty. The valves were all normal and showed no evidence of endocarditis. There was very little evidence of thrombosis in the blood vessels. **Gastro-intestinal tract.**—The liver was somewhat enlarged, appearing firm with a mottled surface. There were no gall-stones. The stomach was considerably enlarged (weight 620 g) with a normal mucosa. The intestines were not abnormal and showed no evidence of inflammation. **Other organs.**—The spleen, suprarenals, heart, kidney, and testes were all normal and none showed any evidence of disease.

**Remarks.**—Sections were cut of the lungs, suprarenals, heart, kidney, spleen, and testes, and stained with haematoxylin and eosin and fast green. **Lungs (Fig. 1).**—The changes were those of an interstitial pneumonitis with a fine reticulation throughout the lung fields and the formation of small nodules. The alveoli contained considerable amounts of eosinophilic albuminous fluid and some small lymphocytes and some

lymphocytes. There was well marked fibrosis between the lung alveoli, and infiltration with mononuclears and some polymorphs was prominent. There were many alveolar phagocytes and some giant cells were also to be seen. Blood vessels were largely normal but a few could be seen, more especially near the small abscesses, in which the muscle coat showed some fibrinoid degeneration with endothelial proliferation. In these there was infiltration of the wall of the vessel by mononuclear inflammatory cells. There was no evidence of tubercle or sarcoidosis. The lymphatic glands showed chronic inflammatory changes only. The pancreas and suprarenals were normal. The heart muscle showed no abnormality but there were one or two small vessels in the fatty tissue immediately next to the muscle which showed changes from the normal. These consisted of mononuclear infiltration in the wall, of endothelial proliferation, and very slight necrosis of the muscle coat. No abnormality in the vessels in the heart muscle itself was found. The kidney showed slight tubular epithelial desquamation and a little lymphocytic infiltration in the interstitial tissue. A few blood vessels showed a change similar to that seen in the sections of the lung and heart. (The appearances were very similar to those depicted in Fig. 15 in the paper of E. F. McKeown, 1947.) The spleen showed a reactive hyperplasia. The appearances in the liver were those of venous congestion. The knee joint showed a typical rheumatoid change with cell proliferation, even to the formation of giant cells in a few places.

### Case 2\*

A female cotton-mill worker aged 48 was admitted to hospital on Dec. 15 1946, complaining of cough, loss of weight, and arthritis. The onset of an acute polyarthritis characterized by pain, swelling and stiffness of the knee joints had occurred for the first time in April 1946, previous to which she had been quite well. During the four weeks following the onset the wrists, elbows and shoulders had been involved. In November 1946 she started to complain of lassitude, palpitations, and dyspnoea and since the onset of the illness she had lost 2 st (12.7 kg) in weight. She gave a previous medical history of recurrent attacks of bronchitis. There was no relevant family history.

On examination there was a morbilliform rash of the arms and trunk, the temperature was 100° F (37.8° C), and dullness and bronchial breathing were present at both lung bases. There was no evidence of abnormality in the heart, abdomen or central nervous system. The blood pressure was 105/60. Pathological investigations at this time showed Hb 70% and white cells 8900. Radiological examination of the chest revealed bilateral basal opacities indicative of consolidation and, above this, marked reticular shadows extending into the mid-zones. Pneumonia was diagnosed and a seven-day course of penicillin was given in spite of which a pyrexia ranging between 99° and 100° F (37.2° and 37.8° C) persisted. Except for occasional rises of temperature to 103° F (39.4° C) the patient remained in this condition until Jan. 16 1947. During this time repeated sputum cultures for tubercle bacilli were negative, the general bacteriological examination of the sputum revealed nothing abnormal and the radiological appearances of the chest remained unchanged on repeated examinations. At the beginning of February 1947 she developed a spiking temperature ranging between normal and 103° F. From this time her condition gradually deteriorated and she became more anaemic. Blood examination showed red cells 2 570 000, Hb 50%, serum albumin 2.2 mg per 100 ml, serum globulin 4.5 mg per 100 ml, serum sodium 320 mEq per 100 ml, chlorides, 533 mg per 100 ml, blood urea 26 mg per 100 ml, W.R. negative. Agglutination tests: *S. paratyphi A* 'H', *S. paratyphi B* 'H', *S. typhi* 'H' negative; 1 in 20 Comp. *S. paratyphi B* 'O', *S. typhi* 'O', *Br. abortus* negative; 1 in 20.

On March 24 oedema of the legs developed and on the 27th the patient died.

\*This case was kindly brought to our notice by Professor Robert Platt of Manchester who, having seen the observations of one of us (Elliott, 1947)—namely, the interpretation of the joint and pulmonary lesions as part of a rheumatoid disease—felt that the case which was in the wards of the Manchester Royal Infirmary under the care of Dr Fergus P. Ferguson was of an analogous nature. We are much indebted to him and to Dr Ferguson for kindly suggesting that we might include the case.

**Post mortem Examination** (performed by Dr J T A Lloyd 36-48 hours after death)—The body was that of a slightly pale middle aged woman. **Respiratory system**—There were a few fine pleural adhesions on both sides, with some 50 ml of straw-coloured fluid on each side. The lower lobes of each lung and the lower part of the upper lobe of the left lung were firm and hard to the touch. They were congested, and also showed small areas of consolidation together with minute abscesses containing a little pus. The appearances suggested a terminal bronchopneumonia with a fibrosing pneumonitis. The remainder of the lung tissue appeared normal. No evidence of tubercle or of sarcoid was seen in the lungs. The trachea was normal. The mediastinal glands draining the lungs were slightly enlarged, but showed no evidence of tubercle. **Cardiovascular system**—The pericardium contained about 50 ml of greenish-yellow clear fluid. The heart was slightly dilated but not enlarged. The myocardium was soft and somewhat pale. The mitral valve cusps were very slightly thickened along the free margins, but no evidence of any endocarditis was present in any valve. The blood vessels showed slight atheroma. **The intestinal tract**

FIG 2—Case 2. Photomicrograph showing interstitial pneumonitis and secondary bronchopneumonia ( $\times 90$ )

was normal throughout. The liver was not enlarged, but showed some degree of fatty change. The spleen was soft and slightly toxic as a result of the pulmonary infection. The kidneys showed no abnormality apart from some degree of pallor. There was a small cervical polypus, but the uterus and ovaries were normal. None of the organs revealed any evidence of tubercle or of sarcoidosis. The brain was not examined.

**Histological Report**—Sections were cut from the kidney, spleen, lung and lymphatic glands from blocks kindly supplied by Professor S L Baker. **Kidney**—There were relatively few changes. Those present consisted of collapsed empty glomerular tufts, some tubular epithelial desquamation, and a few tubular casts. The blood vessels showed some atheroma only. The spleen revealed some reticular-cell proliferation with relatively empty sinuses. The lung (Fig 2) showed considerable general disorganization. The main appearances were those of an interstitial pneumonitis with a terminal bronchopneumonia. The alveoli were of varying sizes, some being emphysematous but many showed infiltration with polymorphs together with some mononuclear cells and also some desquamated alveolar phagocytes. A few of the alveoli were lined with cuboidal epithelium. However, the most striking change was seen in marked interalveolar fibrosis, with fairly well developed fibrous tissue which was infiltrated with mononuclear cells, plasma cells, and a few polymorphs. The blood vessels showed no change from the normal except that in one large vessel there was a little atheroma. There was no evidence of tubercle or sarcoidosis. The mediastinal lymphatic glands showed some chronic inflammation only.

### Case 3

A housewife aged 55 was admitted into the rheumatism unit under the care of P E on Sept 26, 1946, when she complained of pain, swelling and stiffness of the hands, shoulders knees and feet of three months duration. There was no history of a precipitating factor in the form of an acute infection. Frequent attacks of tonsillitis had occurred during the past few years.

On examination she was thin and wasted, weight, 6 st 9 lb (42.2 kg). No clinical abnormality was present in the heart, lungs, abdomen, or central nervous system. Examination of the locomotor system showed fusiform interphalangeal joint swellings and a swollen flexed left knee-joint. There was no lymphadenopathy.

Radiological examination of the chest showed no gross abnormality (Fig 3). There were some calcified hilar foci, those of the hands and wrists showed osteoporosis and narrowing of the joint spaces.

Pathological investigations showed ESR, 60 mm in the first hour (Westergren), red cells, 5,920,000 per cmm, Hb, 102%, C.I., 0.85, white cells, 22,200 per cmm (polymorphs 68%, lymphocytes 26%, monocytes 6%, eosinophils, 2%). Gastric residue before histamine free HCl, nil, total acidity, 18 ml N/10. Gastric residue after histamine free HCl 22 ml N/10, total acidity 44 ml N/10. Urinalysis NAD. Throat swab no Klebs Loeffler bacilli or haemolytic streptococci grown on Oct 4, 1946. Copious growth of haemolytic streptococci on Nov 27, scanty growth of haemolytic streptococci on Dec 5, WR and Kahn negative, serum uric acid, 2.6 mg per 100 ml alkaline phosphatase, 7.5 units.

The patient's general condition remained the same until June 12, 1947, when she complained of cough with sputum, sweating, and loss of weight of 7 lb (4.5 kg). There were now scattered rales throughout both lung fields, and the breath sounds were bronchovesicular in type. Serial skiagrams were unchanged until the one on June 16 which showed widespread heavy reticulation and apparent miliary mottling throughout the whole of both lung fields (Fig 4). A presumptive diagnosis of pulmonary tuberculosis, Boeck's sarcoidosis or polyarteritis nodosa was made. Repeated sputum examinations and Loewenstein's culture together with gastric lavage and concentration techniques failed to

FIG 3—Case 3, Oct 1 1946. Radio graph of chest showing no gross abnormality.

FIG 4—Case 3, June 16 1947. Radio graph showing widespread heavy reticulation and miliary mottling throughout both lung fields.

reveal the presence of tubercle bacilli. General bacteriological examination of the sputum revealed no abnormality. On Aug 30 there was no significant change, and the radiological appearance of the lungs was regarded by several experts as being compatible with that of polyarteritis nodosa. A further radiograph on Jan 16, 1948, showed the lung fields to be cleared a little, but heavy reticulation was still present. The patient now weighs 6 st 2 lb (40 kg), but her general condition is fundamentally unchanged.

### Discussion

In a recent discussion on the aetiology of chronic rheumatism one of us (Ellman, 1947) suggested that the theory of bacterial allergy or that due to foreign protein or hormones provided an attractive and rational aetiological basis for this rheumatoid state and at the same time strengthened the unitary theory. Fundamentally the acute and chronic rheumatisms may be regarded as anaphylactic diseases with multiple lesions in the mesodermal system produced by continual antigen-antibody reactions in or on tissue cells. Visceral and other lesions may be explained as hypersensitivity manifestations in tissues elsewhere in the body. Some co-ordination is thereby provided for the rheumatoid group of diseases and suggests a relationship between the acute rheumatoid type of arthritis and rheumatic fever.

It is possible, too, as has been suggested by Parkes Weber (1946), that the syndromes of a recurrent and transitory nature included under the term "palindromic rheumatism" of Hench and Rosenberg (1944) can be extended to include the so called intermittent hydrarthrosis, serum joint disease, allergic arthritis, and allied syndromes. Again, the work of Rich and Gregory (1943, 1946) and their co-workers has indicated an even wider association on the basis of hypersensitivity between the rheumatoid type of arthritis and such hitherto obscure conditions as scleroderma, dermatomyositis, polyarteritis nodosa, and acute disseminated lupus erythematosus. Bohrod (1947) has described their essential lesions as "rheumatoid granulomata," and Cecil (1946) refers to "these rheumatoid diseases of the collagen matrix." In clinical practice we have been impressed on more than one occasion by the association of scleroderma with a rheumatoid type of arthritis (Ellman and Parkes Weber, 1948). While the experimental production in rheumatic fever of anaphylactic pulmonary lesions with a peculiar type of "pneumonitis" has received some attention (Rich and Gregory, 1943, 1946), pulmonary and other lesions are now known to occur also in such widespread systemic diseases as polyarteritis nodosa (Daley and Miller, 1946) and disseminated lupus (Rakov and Taylor, 1942; Klemperer, 1948).

So far as the lung lesions are concerned, Gouley (1938) and Neuburger *et al* (1944) found histologically in "rheumatic pneumonia" three successive stages of change in the interalveolar septa: (1) fibrinoid necrosis in collagen, (2) infiltration with round cells, plasma, and giant cells, (3) fibroblastic proliferation and fibrosis. All these are essentially changes in the collagen matrix.

In support of the anaphylactic or hypersensitivity theory in the mechanism of production of these lesions Rich and Gregory were able to carry out necropsy studies on patients with serum sickness. They found changes in the endocardium, myocardium, and pericardium, all of which were histologically indistinguishable from those in rheumatic fever. Further experiments have been carried out on animals rendered anaphylactic with horse serum or egg albumen. Similar changes were again produced in the heart, and more recently pulmonary lesions characterized by interstitial fibrinoid necrosis.

From those observations, and in view of the widespread systemic nature of some of the cases, it will be understood

how the term "rheumatoid arthritis" is really misleading. "Rheumatoid disease" may be open to criticism, but it is preferable as the parent term, with joint lesions seen as the principal clinical manifestation, in the same way that the term "gout" describes the parent lesions of a metabolic dysfunction whose principal clinical manifestation is the joint involvement.

The three cases we have described exhibit common features in what appears to have been the development of lung lesions during the early active phase of the joint process. In Case 3 the onset of the lung disease is known from the serial radiographs to have occurred nine months after the onset of the polyarthritis, and attention was drawn to it by the symptomatology of cough, dyspnoea, and weight loss initially ascribed to possible pulmonary tuberculosis. All investigations disproved this diagnosis, likewise the possibility of Boeck's sarcoidosis. A consensus of expert opinion on the radiological appearances of the lung reticulation has favoured the diagnosis of polyarteritis nodosa, and the relationship of this condition with the "rheumatoid granulomata" is of considerable interest. It would be fair to postulate a hypersensitivity phenomenon involving equally the joint and lung tissues. In Case 2 symptoms referable to the pulmonary disease occurred six months after the onset of the polyarthritis. The radiological lung changes were those of a basal reticulation. Unfortunately no radiograph of the chest before this time is available.

In all three cases the clinical course is similar, the joint lesions preceding the pulmonary lesions, and one might not unreasonably assume, without wishing to appear to be in any way dogmatic, that the joint and lung lesions are manifestations of one and the same pathological process.

Studies of the two cases that came to necropsy present certain features in common, also suggestive on histological investigation and predominantly evident in the lungs, where fibroblastic thickening of the alveolar walls (chronic fibrosing pneumonitis), plus infiltration by mononuclear, plasma, and occasional polymorph cells, was present; the kidney in Case 1 revealed fibrinoid necrosis in a few blood vessels. This case also showed similar changes in blood vessels at another site—namely, in the fatty tissue immediately next to the heart muscle. In both cases the section of the lung has shown a chronic fibrosing type of "pneumonitis." It was certainly not sarcoid, and at the same time was rather different from the "rheumatic pneumonia" of acute rheumatic fever. Our own opinion was that the lung changes could not be dissociated from Gouley's Stage 3, already described, where interalveolar fibroblastic proliferation predominated on histological examination. However, it cannot be held that this histological change is specific by itself, but its being coupled with the necrosis found in the muscular wall of the artery in other parts of the body suggests that an acute arteritis had been present in the past as part of a fibrinoid necrosis. These arterial changes were found only after careful and thorough search, and, taken together with the lung lesions, would appear to suggest a widespread disseminated lesion. Further than that we are not prepared to go from the pathological studies alone. However, on clinical grounds the similarity of the lung lesions is undoubted, and many features of one are mirrored in the other.

It is of interest to note that Klemperer has recently reported a case of disseminated lupus erythematosus with lung lesions where the histology was of a fibrinoid necrosis in the interalveolar septa. A similar pathological process has been observed in the allied group of so-called granulomata already noted.

### Summary

The widespread systemic nature of certain cases of rheumatoid arthritis has been noted

It is suggested that 'rheumatoid disease' is a preferable term whose principal clinical manifestation is arthritis

Three cases of joint and lung lesions are recorded and it is suggested that they are among the clinical manifestations of 'rheumatoid disease'

We are greatly indebted to Dr J N Cumings for help on the pathological side, for the photomicrographs, and for his close study of the histology of Cases 1 and 2 to Dr A Signy for much helpful criticism, to Professor Robert Platt for kindly allowing us to include Case 2, and to Dr G Batten for help on the radiological side

## CORD COMPLICATIONS DURING PREGNANCY AND LABOUR

BY

JOYCE MORGAN, MD, BSc, MRCOG  
 Obstetrician Hillingdon County Hospital Uxbridge

Considering the length and slenderness of the umbilical cord, it is surprising that cord complications do not occur more frequently. Prolapsed cord, which is the commonest of these complications, occurred in only 50 cases out of a total of 10,000 deliveries—i.e., 0.5%. Munro Kerr (1937) gives an incidence of 0.25% and DeLee (1943) an incidence of 0.8%.

The 42 cases treated in this hospital are listed in Table I. Eight patients were admitted with dead babies and therefore received no special treatment. A summary of the 50 cases is given in Table II.

Three of these cases are given in further detail because of their special interest.

**Mrs A** aged 35 2-gravida, married 12 years. Admitted with severe pre-eclamptic toxæmia, not improved by rest. Surgical induction performed at 28 weeks with a Drew Smythe catheter. At half dilatation, hand and cord prolapsed beside head. Attempt at reposition unsuccessful. Forceps then applied to foetal head but though small, the head was too large to be delivered through the thick half dilated cervix. Two incisions made in cervix and infant, weighing 2 lb 8 oz (1.13 kg) delivered alive. Cervix sutured. Mother made uneventful recovery. Infant lusty at birth and remained healthy. It is now 2 years old.

This delivery may appear to be rather heroic treatment but is justified by results.

**Mrs B** aged 28 2-gravida admitted at term as a transverse lie. External version to vertex performed, and patient sent to x-ray department for pelvimetry. Membranes ruptured and cord prolapsed while patient was on the x-ray table. Patient was returned to the ward in the knee-chest position and the cord replaced through a quarter-dilated cervix. Pulsation in

the cord returned after reposition and caesarean section was performed. At operation the cord was found to be stretched tightly across the head, and the child was still born.

**Mrs C** aged 26, primigravida term. Breech presentation at term. Fairly easy external version to vertex, but foetal heart became irregular and slow. A few minutes afterwards the heart returned to normal and the foetus was left as a vertex with the head above the brim. Membranes ruptured early in labour, and the foetal heart became irregular. The head was still high but when it was pushed down into the pelvis with a hand above the symphysis the foetal heart stopped altogether returning as soon as the pressure was released. It was decided that this was the so-called 'occult type' of prolapsed cord—i.e. the cord was probably nipped between the foetal head and the pelvic brim. Caesarean section was therefore performed and a healthy infant obtained. The cord was twisted loosely round the child's body, but the actual prolapsed loop was not seen, as it would be dislodged as the head was delivered.

Apart from prolapse of the cord, the following cord complications can occur.

### Cord Round Neck or Body

With an active foetus, or with repeated antenatal versions, the umbilical cord may be wound round the neck or body once, twice, or three times. Only once have I seen the cord four times round the neck of the foetus. Strangulation *in utero* or during birth may result. This condition of the cord is usually recognized only during labour or at delivery, but in a few cases it can be diagnosed during pregnancy. The following three cases illustrate the point.

**Mrs D** aged 35, primigravida, breech presentation at term. Easy antenatal version, but directly after version the foetal heart dropped to 80. The heart rate gradually returned after a few minutes and the foetus was left in the vertex position. Labour started spontaneously a few days later. Delivery was normal, after a rapid labour, but the infant was stillborn, with the cord tightly round the neck twice.

**Mrs E** aged 35, primigravida. Breech presentation at 36 weeks. Easy antenatal version, but foetal heart stopped. Foetus was turned back to a breech, and the heart restarted as soon as the foetus reached the transverse position. This manoeuvre was repeated the following week with exactly the same result. It was therefore concluded that the foetus had a short cord or the cord was round the neck and that this would cause delay in delivery and probably stillbirth. It was decided to deliver by caesarean section at term. At operation it was found that the cord was twice round the infant's neck and that there was an area of haemorrhage at the root of the cord where it had been pulled upon during the antenatal version. The infant was healthy, weighing 6 lb 15 oz (3.15 kg) and the mother made an uninterrupted recovery.

**Mrs F** aged 34, primigravida term. Breech presentation. Easy version, but foetal heart dropped to 100 and became muffled and irregular. The foetus was turned back to a breech. A second attempt a few minutes later produced the same result so that the foetus was left as a breech. In this case also caesarean section was performed at term, and the cord was found to be wrapped round the neck and body. The infant was healthy, and the mother made a satisfactory recovery.

Over-activity of the foetus with self-strangulation is illustrated by the next case.

**Mrs G** aged 29, 2-gravida. At 38 weeks the head was high and the foetal heart was heard. The patient was healthy with a blood pressure of 120/68, no albuminuria, and a negative Wassermann. Three days before term the foetus became increasingly active and then all movements suddenly stopped. Labour began spontaneously, and when the membranes ruptured the liquor was deeply stained with meconium. The infant was stillborn and macerated, and the cord was wound tightly round the neck three times, with tension at the umbilicus.

Cord round the neck, apart from causing foetal distress, may prevent engagement of the head and so increase the duration of labour.

TABLE I—Summary of Cases

Gravid	Maturity (Weeks)	Presentation	Dilatation	Method of Delivery	Infant
2	28	Head hand and cord	Half	Dilatation of cervix forceps delivery	2½ lb (1.13 kg) Healthy lived
1	28	Vertex	2 fingers	Internal version after reposition of cord	3 lb 9½ oz (1.63 kg) S.B.
1	38 (twins)	Breech (1st twin)	Full	Normal delivery	4 lb (1.8 kg) S.B.
1	28	Transverse		Internal version to breech normal delivery	2½ lb (1.13 kg) S.B.
2	28	Vertex acute hydramnios		Normal	2 lb (0.9 kg) S.B.
1	34	Vertex			4 lb 4 oz (1.9 kg) Healthy
4	36				4 lb 13 oz (2.18 kg) Healthy
1	SI with Drew Smythe catheter for toxæmia				
1	31				
1	Acute pyelitis				
1	36		1 finger	Caesarean	3 lb 15 oz (1.78 kg) Alive, but died during 1st week
1	Induction with D S C for toxæmia				4 lb 10 oz (2.1 kg) Healthy
2	Term	Transverse	Three-quarters	Internal version to breech manual delivery	7 lb 6 oz (3.35 kg) Healthy
1		Vertex	Half	Dilatation of cervix and forceps delivery	7 lb 1 oz (3.2 kg) Healthy
2	40		Three quarters	Forceps	7 lb 10 oz (3.46 kg) S.B.
3	40		Prolapse during surgical induction	Internal version to breech normal delivery caesarean not contemplated because of patient's general condition	9 lb 9 oz (4.34 kg) S.B.
2	40		Full	Forceps	6 lb 12 oz (3.06 kg) Healthy
1	40				6 lb 2 oz (2.78 kg) Healthy
1	40		One-quarter	Caesarean	7 lb (3.17 kg) Healthy
2	40	Breech	Full	Forceps	6 lb 9 oz (2.98 kg) Healthy
2	40	Vertex	One-quarter	Caesarean	7 lb 7 oz (3.37 kg) Healthy
1	40	Breech	Full	Forceps	7 lb 8 oz (3.402 kg) Healthy
1	40	Vertex			5 lb 10 oz (2.55 kg) Healthy
4	36		One-quarter	Caesarean	7 lb 5 oz (3.32 kg) Healthy
2	SI for toxæmia				
2	40	Transverse	Full	Internal version to vertex forceps	7 lb 3 oz (3.26 kg) Healthy
5	40		Three-quarters	Internal version to breech manual delivery	11 lb 3 oz (5.07 kg) S.B.
2	36				7 lb (3.17 kg) S.B.
2	40	Vertex		Forceps	6 lb 12 oz (3.06 kg)
2	40		One quarter	Caesarean	S.B.
1	34 (twins)	Breech (1st twin)	Full	Manual delivery with forceps to after coming head	5 lb 11 oz (2.58 kg) Healthy
1	40	Vertex	Onset of labour	Caesarean	Healthy
1	40		Half	Forceps on full dilatation	6 lb (2.72 kg) S.B.
2	40		Full	Forceps	6 lb 4 oz (2.83 kg) Healthy
2	40		Full	Caesarean	7 lb (3.17 kg) S.B.
2	40	Transverse (2nd twin)	Onset of labour	Internal version to vertex forceps	7 lb (3.17 kg) Healthy
2	40		Full	Manual dilatation of cervix internal version to breech manual delivery	8 lb 4 oz (3.74 kg) Healthy
2	40		Half		
1	40 (twins)	Breech (2nd twin)	Full	Manual	5 lb 8 oz (2.5 kg) Healthy
1	40	Vertex		Forceps	7 lb 9 oz (3.43 kg) Healthy
5	40				7 lb (3.17 kg) S.B.
2	36		One third	Manual dilatation of cervix and forceps	4 lb 12 oz (2.15 kg) Alive
2	SI for toxæmia and Rh neg blood				Died of cerebral haemorrhage
2	38 (twins)	Hand foot and cord (2nd twin)	Three-quarters	Manual dilatation of cervix forceps	7 lb 8 oz (3.4 kg) Healthy
2			Full	Internal version to breech manual delivery	6 lb 11 oz (3.03 kg) Healthy
2	36 (twins)	Transverse		Internal version to breech manual	3 lb (1.36 kg) Alive Died of cerebral haemorrhage
2	SI for toxæmia				4 lb 4 oz (1.9 kg) Alive Died of cerebral haemorrhage
2	37 (twins)	Vertex		Normal	6 lb 8 oz (2.95 kg) Healthy
3	SI for toxæmia				
3	36		During induction of labour	Caesarean	

TABLE II—Prolapsed Cord

Method of Delivery	Alive	Stillbirth	Neonatal Death	Total
Natural forces	4	9 (8 dead on admission)	1	13
Forceps	13	5	1	18
Caesarean	6	2	—	8
Internal version and manual delivery	5	6	1	11
	28	22	3	50

Living 56% S.B. 44% NND 3% Foetal salvage 50%

Mrs H, aged 24, primigravida, had a labour lasting 48 hours. There was delay in descent of the head, and foetal distress developed early in the second stage. Forceps were applied and a healthy infant delivered weighing 6 lb 11 oz (3.03 kg). The cord was short and was round the neck preventing descent of the head and causing foetal distress.

Mrs I aged 38, primigravida, term. Head high throughout pregnancy and during labour. Pains fairly strong after rupture of membranes but no descent of the head. Foetal distress appeared and caesarean section was performed. At operation the cord was found to be wrapped four times round the neck, preventing descent of the head and causing foetal distress. The infant was shocked at birth, but recovered. The mother made an uninterrupted recovery.

Foetal distress was the only sign in the following three cases.

Mrs J aged 32 primigravida 36 weeks. Foetal distress at full dilatation. Foetal heart rate 80 with passage of thick meconium. Forceps delivery performed. No disproportion.

but cord round the neck and both arms, and pulsating feebly. Pulsation restarted strongly when cord was unwound. The infant was healthy and weighed 4 lb 7 oz (2 kg).

Miss K aged 23, primigravida. Severe pre-eclamptic toxæmia at 36 weeks, with spontaneous onset of labour. Labour progressed normally until the end of the second stage, when the foetal heart suddenly stopped. The infant was still-born, with the cord very tightly round the neck.

Mrs L aged 34, primigravida. Labour started spontaneously, but foetal distress occurred at the beginning of the second stage. Forceps were applied, and a healthy infant weighing 5 lb 15 oz (2.7 kg) was delivered. There was no disproportion, but the cord was wound tightly round the neck causing foetal distress.

These last few cases show the importance of frequent auscultation of the foetal heart throughout the second stage of labour and the need to have everything ready for a rapid forceps delivery in such an emergency.

A short cord may cause delay in descent of the head and foetal distress, but I have not had a case of this sort requiring operative intervention in my series.

**True Knot in the Cord**—A true knot in the cord is often seen after delivery, but in most cases it is formed during delivery, when a loop of cord is slipped over the infant's head or shoulders. True knots can occur *in utero*, especially after antenatal version or with a very active foetus. I have myself seen only one case of a true knot which might have been the cause of stillbirth, but this occurred in a patient with severe pre-eclamptic toxæmia. There was a tight knot in the macerated cord, but death

might have been due to maternal toxæmia. A case of true knot in the cord causing foetal distress during labour was described recently by Price (1947).

### Incidence of Cord Complications

Cord complications are rare, but the foetal death rate due to them is very high. DeLee gives the foetal death rate in treated cases as 40-50% and in untreated cases as 80%. In this series the foetal death rate in treated cases was 40.5%. Because of this rarity it is difficult for any one person to get sufficient experience in the treatment of cord complications, and this is one reason why the foetal death rate will always remain high. Early diagnosis and adequate treatment are essential, and two necessities for treatment are an intelligent and well-trained nursing staff and a resident obstetrician.

### Diagnosis and Treatment

The diagnosis of prolapsed cord may be made first by seeing the cord presenting at the vulva. More commonly the first indication is slowing of the foetal heart, the cord being found on routine vaginal examination. In a few cases the cord is nipped at the pelvic brim and cannot be felt with the examining finger.

The treatment of prolapsed cord depends on the presence or absence of foetal heart sounds and on the degree of dilatation of the cervix. In all cases except where the cord is macerated the patient is placed in the knee-chest or the high Trendelenburg position while preparations for further treatment are being made. Pressure on the cord can further be relieved by the operator inserting two fingers into the vagina and holding up the presenting part above the brim. Even when pulsation has ceased, relief of pressure on the cord sometimes restores the circulation, but the foetus cannot stand total obstruction of the cord for more than a very few minutes. The knee-chest or Trendelenburg position, though useful in an emergency, can be maintained for only about 10 to 15 minutes without great discomfort to the mother. When operative intervention is to be used the patient can be anaesthetized in the Trendelenburg position, and should be moved only when the operator is ready to begin. If the cervix is as much as three-quarters dilated, then immediate delivery is performed—by forceps in a vertex presentation or by manual delivery of a breech or transverse lie. In such circumstances there is no need to waste time trying to replace the cord. When the cervix is less than three quarters dilated the difficulties are increased.

Reposition of the cord can be attempted, but this, easy in theory, is very difficult in practice, and the actual reposition may cause further foetal distress by pressure and kinking. If this method is tried the hand is the best repositor, but the cord is an awkward and slippery organ with a will of its own. The foetal heart must be counted at least every five minutes after reposition in case of further pressure as labour progresses. In one case it seemed to me to be a good idea to give an injection of nikethamide into the cord before reposition, and this was tried. The foetal heart improved in tone and frequency, but the cord continued to bleed at the site of injection.

Internal version to a breech presentation is not satisfactory. The idea is that the breech fits less closely into the brim and so leaves more room for the prolapsed cord. In practice this does not work very well, because the cord may become entangled round one leg or the child may sit down on it at the level of the brim.

Caesarean section is the method of choice when the cord is pulsating strongly, the cervix is less than three-quarters dilated, the operating theatre is available and the operation

is quick. It is no good subjecting a mother to caesarean section for prolapsed cord if the infant is going to be still born. She can have her stillborn infant without the added discomfort of an abdominal incision.

There were no maternal deaths in this series. Though the foetal results are poor, they can be improved by constant watchfulness on the part of the midwife and by quick and accurate diagnosis by the obstetrician, with minimum delay in treatment.

## HODGKIN'S DISEASE CONFINED TO THE JEJUNUM

BY

G. L. ROBINSON, MD

Pathologist to the Seamen's Hospital Society

The subvariety of Hodgkin's disease affecting the alimentary tract, though by no means excessively rare, is better described in journals than in textbooks. A clear outline of its features, with references to date, is given by Havden and Apfelbach (1927), who selected 26 previously reported cases for their study, adding three of their own. Spleen and liver are not enlarged and nodules within them are uncommon, mesenteric but not other groups of lymph nodes are involved, lesions in the gut tend to be multiple and small, starting in the mucosa or submucosa, forming an ulcer with an enclosing "wall," and quickly penetrating muscular and serous coats; histologically, lymphocytes and endothelial cells predominate, while Sternberg-Reed cells are scanty, symptoms are intestinal and not of long duration, death often follows perforation or haemorrhage, or is cachectic.

The case here presented conforms to the above description and is very similar to that published (without necropsy) by Badia (1943) of a woman aged 29, with a six-months history, who died seven weeks after a loop of small intestine had been resected and diagnosed histologically as Hodgkin's sarcoma of the jejunum.

### Case Report

A ship's chief wireless operator, aged 51, was admitted to the Dreadnought Seamen's Hospital on June 20, 1947, with a three months history of burning epigastric pain two hours after meals, loss of 1 st 7 lb (9.5 kg) in weight, loss of appetite, and weakness of the legs when climbing ships ladders. Vomiting had not occurred and the bowels were regular. Except for pneumonia eleven months before (Long Island College Hospital), his health had been good. His mother had died at 84 (heart) and father at 79 (cancer of stomach), two brothers and a sister were alive and well. Physical examination revealed wasting, very bad teeth, and no palpable glands. Weight was 6 st 12 lb (43.5 kg), blood pressure 110/70 mm Hg, pulse 100 (and higher thereafter), temperature 96.2° F (35.7° C), but between 99 and 102° F (37.2 and 38.9° C) thereafter.

The following investigations were carried out. Radiograph of chest chronic bronchitic changes. Barium meal stomach and duodenum appear normal. Barium enema there is a filling defect in the sigmoid. Urine no chemical or microscopical abnormality. Wassermann and Kahn negative. Alcohol histamine meal no abnormality. Blood count haemoglobin 53% (Haden), RBC 3.2 millions and WBC 6200 per cmm, colour index 0.83. Sedimentation rate (Westergren) 24 mm at one, 49 mm at two hours. Blood urea 30 mg per 100 ml. Plasma protein 5.25% (albumin 3%, globulin 2.25%).

= 13) Occult blood strongly positive benzidine test, negative amidopyrine test Sputum four times negative for tubercle

Carcinoma of the colon was diagnosed and laparotomy was performed (July 8) after transfusion had raised the haemoglobin level from 47 to 61% (Haden) An adhesion between sigmoid and small intestine was freed and the resulting hole in the colon closed An abscess cavity was found in the mesentery to which small intestine was bound The loop and mesentery

Photomicrograph showing the disease process in the mesentery adjacent to the surgically excised loop of jejunum ( $\times 190$ )

were resected, and from them a histological diagnosis of Hodgkin's disease was made (see Fig) The patient died on the fifteenth post operative day

The specimen removed at operation consisted of a piece of jejunum 24 cm long with attached mesentery up to 5.6 cm wide, incised about midway, where the gut was thickened, haemorrhagic, and bunched by fibrosis, to show a brawny bile stained excavation, defined by scar tissue, extending 3 cm from the incised gut into the mesentery A ragged gaping hole, occupying most of the free aspect of the thickened jejunum opposite this excavation, was caused by surgical dissection There was thus evidence of a swollen, fibrosing, penetrative lesion encircling the middle 5 cm of the loop of gut resected and rather abruptly demarcated from the remaining gut, which was of normal appearance The lymph nodes in the attached mesentery were enlarged up to 1.3 by 0.8 by 0.7 cm and showed uniform yellow glistening cut surfaces

The necropsy showed general purulent peritonitis, with a number of tough fibrous adhesions in addition to the fibrin binding loops of the small gut These adhesions were found to occur on the serosal aspect of ulcers in the upper jejunum where roughening slight puckering, and fibrous tags but no tubercles were seen There was no gross abnormality of stomach or duodenum The uppermost lesion was a shallow ulcer, 1 by 0.6 cm, situated a few centimetres beyond the duodeno jejunal flexure with its axis transverse to that of the gut with its floor short of the muscularis, and with its edges sheer This was the only ulcer without accompanying fibrous adhesions on the serosa The next lesion, 80 cm below the flexure, was the anastomosis representing the site of the surgically excised loop, with considerable sepsis in the adjacent mesentery Below this, at a point 140 cm (pre-operatively 164 cm) from the flexure, came a group of four small ulcers (largest 0.8 cm diameter) of punched-out appearance, with sloughing floors piercing the muscularis An area, about 2.5 cm in diameter, of faint white stippling could be seen infiltrating the mucosa throughout this ulcer-bearing zone when it was brightly illuminated, there were also a few slit-like erosions about 1 mm long Below this group 170 (pre-operatively 194) cm from the flexure was a single girdle-type ulcer measuring 2 by 0.8 cm with its floor penetrating the muscularis and with its edge raised swollen and mainly rounded, smooth, and tense looking though eroded in places Another similar

though slightly smaller ulcer occurred 200 (pre-operatively 224) cm below the flexure Next below this, 230 (pre-operatively 254) cm from the flexure, came the largest of the lesions, which consisted of an ulcer, 6.2 by 2.2 cm, encircling the gut for about two thirds of its circumference In contrast with the other lesions the ulcer floor was in this case hypertrophied, so that it stood up as a plateau 0.3 cm above the mucous membrane, it was coarsely nodular, fissured, and stained slate-colour by altered blood A smooth, tubular, and slightly undermined edge, itself ulcerated in places, surrounded it like a rail Two more adjacent punched-out ulcers (the larger measuring 1 cm in its longer axis, transverse to the gut) were found beyond this at a distance of 240 (pre-operatively 264) cm below the flexure, and here the lesions ceased A short Meckel's diverticulum was present The colon was distended by pale sprue-like faeces Mesenteric lymph nodes were moderately enlarged up to 1.8 by 1.5 by 1.2 cm and showed uniform yellow cut surfaces There was no enlargement of other groups The spleen was firm and below normal size

### Comment

The histology of Hodgkin's disease is present only in sections of the gut lesions, the affected piece of mesentery (where the picture is most typical), and the larger of the mesenteric lymph nodes In most sites the changes appear to be early and rather atypical In some nodes large Hodgkin-like cells are scattered diffusely and the cells of the sinuses are proliferating without destruction of normal architecture Fibrosis in the nodes is only beginning, and typical giant cells have to be searched for Sections of the ulcers show necrosis of the base with replacement of all coats by granulation tissue containing a variety of chronic inflammatory cells together with small hyperchromatic giant cells, and affected by pyogenic infection to varying degrees In one cut, at the periphery of an ulcer, the muscularis mucosae is seen breaking up beneath a mucous membrane which is still intact In all regions there is a prominence of cells of reticulo-endothelial type, as noted by Hayden and Apfelbach (1927) and also mentioned in the report of a case of gastric Hodgkin's disease by Jungmann (1943) These cells, tending to be diffusely scattered, to show distinctly eosinophil cytoplasm and rather well-defined outlines, sometimes look at first glance like the expected infiltration of eosinophil polymorphs, which is not a noticeable feature in these sections Intravascular plugs of granulation tissue, sometimes mixed with thrombus, are common and often contain small hyperchromatic giant cells It seems possible that this invasiveness for blood vessels may by infarction play a part in the production of the ulcers Vascular penetration has been photomicrographed both by Donati and Bragaglia (1942) in an intestinal case and by Bini and Parvis (1940) in a gastric case Histological malignancy is stressed in both these cases In the present case the short history, the small hyperchromatic giant cells, and the cellular rather than fibrotic reaction are held to indicate simply an early and acute form of Hodgkin's disease

The Third Annual Report of the Liverpool Cancer Control Organization has some interesting figures relating to cases of cancer referred for treatment during 1944 Among 2,668 cases the disease was so advanced as to render treatment impracticable in 993 Of the 1,675 cases in which treatment could be undertaken there were only 971 in which the condition was at a sufficiently early stage to warrant radical curative treatment being attempted Of the 971 cases so treated 72 subsequently died of intercurrent disease or were lost sight of There remained for review 899 patients, of whom 617 were alive three years after the start of treatment

## Medical Memoranda

### Traumatic Rupture of Bowel in Inguinal Hernial Sac

Factors predisposing to this injury are irreducibility of the hernia, distension of the bowel, and nipping of the bowel against the unyielding surface of the pubic bone. A truss may therefore be a source of danger if it does not completely control the hernia and if the patient sustains an injury which presses the truss and, in turn, the bowel back against the pubis.

The following case shows that rupture of the bowel may occur in these circumstances and may lead to a fatal result.

#### CASE HISTORY

A man aged 76 had worn a truss over a right oblique inguinal hernia for 30 years. On April 4, 1947, he tripped and fell forward on his face. Immediately after the fall he felt a dull constant pain in the hernia, which had come down. He therefore reduced the hernia without difficulty, although a small lump remained. Severe epigastric pain soon began, at first this was made worse by movement and relieved by lying down, but within half an hour of the accident it appeared to assume a colicky nature, causing the patient to roll in agony. He vomited twice and went to bed. During the night the pain gradually subsided, but vomiting was repeated three or four times. The next day he experienced stabbing pains on movement, and when he coughed there was pain in the hernia. Vomiting continued and his doctor attempted, without success, to reduce the lump in the right inguinal region.

On admission to hospital 30 hours after his fall the patient complained of generalized abdominal pain, which was constant and was made worse by movement. His bowels had not functioned since the accident.

On examination he was very short of breath and had a constant cough with white mucous expectoration. The tongue was dry and furred, temperature  $97.6^{\circ}\text{F}$  ( $36.4^{\circ}\text{C}$ ), pulse 106, respirations 45. Cardiovascular: Blood pressure 135/85, no oedema, slight cyanosis, cardiac enlargement to left (apex beat  $4\frac{1}{2}$  in (11.25 cm) from midline). Lungs: Normal percussion note, breath sounds vesicular, basal rales, scattered rhonchi, both inspiratory and expiratory. Abdomen: Did not move on respiration, slight distension, no visible peristalsis, generalized tenderness and rigidity, most pronounced on right side, marked hyperaesthesia in right iliac fossa. Per rectum: Tenderness in pouch of Douglas, no mass palpable. Over the external inguinal ring there lay a slightly tender lump,  $1\frac{1}{2}$  in (3.75 cm) in diameter. A diagnosis of peritonitis due to perforated gut was made.

Operation—Laparotomy was undertaken under spinal anaesthesia (Dr Henry Williams). A right lower paramedian incision was made and the tissues at the lower end were stripped down so as to expose the inguinal lump. This consisted of bruised and oedematous sac and appeared to be empty. On incising the peritoneum a large quantity of thin purulent fluid escaped. Coils of small intestine were found lightly adherent and bathed in pus in the right iliac fossa. Generalized peritonitis was present. A perforation  $\frac{1}{2}$  in (1.25 cm) in diameter a few feet above the ileocecal junction was closed with two layers of sutures. As the patient's condition at this stage was very poor the neck of the empty hernial sac was rapidly closed with cotton sutures applied from the abdominal aspect and the abdomen was closed with drainage of pelvis and wound. On return to the ward he was in poor condition—blood pressure was 60, pulse 120, with frequent dropped beats.

On April 6 the blood pressure was 130/78, pulse 110, apex rate 120. Auricular fibrillation occurred and 'digoxin,' 0.5 mg intravenously was given, being repeated eight hours later. Next day the patient was irrational. Pulse was regular at 120. At 10.30 a.m. he suddenly became dyspnoeic and cyanosed, and died. Permission for necropsy was refused.

#### COMMENT

There is no direct proof that the ruptured loop of ileum occupied the hernial sac at the time of injury. On the other hand the initial pain was felt in the hernia and abdominal symptoms did not supervene until after its reduction. These facts together with the bruised condition of the sac as seen at operation make it highly probable that rupture took place in the sac. It is suggested that the bowel was nipped between the head of the truss and the pubic bone.

I am indebted to Dr J. Thomson, medical superintendent of Dunedin Hospital and to Professor Gordon Bell for permission to publish these notes.

Late Resident Surgical Officer and Tutor  
Dunedin Hospital, New Zealand

### Sternal Swelling as a Presenting Sign of Hodgkin's Disease

Goldman and Victor (1945), in reviewing the salient features of Hodgkin's disease, stress the importance of involvement of sternal nodes in that they accept it as a pathognomonic sign. All glandular areas may be enlarged in Hodgkin's disease, but involvement of sternal nodes might easily be overlooked and it is my impression that the frequency of its occurrence is not appreciated enough. Experience has taught me to look for enlargement of the sternal nodes along the course of the internal mammary artery in each case suspected of this disease. If these glands are involved there may be a firm swelling at the level of the second and third intercostal spaces fixed to the underlying chest wall.

In treating several hundred cases of Hodgkin's disease with deep x-ray therapy I can say that roughly 15% of my patients at some stage showed an involvement of these lymph nodes, but in one case I found it to be a presenting sign. The following is the history of this case.

#### CASE REPORT

On Nov. 20, 1946, a girl aged 15 attended the out-patient department of the Coventry and Warwickshire Hospital complaining of general weakness, slight loss of weight, unproductive cough, and a painless "swelling on the chest" which had appeared two weeks previously.

On examination a firm swelling lateral to the sternum was found at the level of the second intercostal space. Clinical examination of chest, heart, etc., revealed nothing abnormal. Radiography of chest and ribs revealed an azygos lobe and normal pulmonary fields, no enlargement of hilar glands, and a destructive lesion in the anterior end of the second right rib. A blood count showed 12,800 white cells, otherwise there was no abnormality. The ESR was 23 mm in the first hour. The Wassermann reaction was negative.

The patient was admitted to hospital, and exploration of the swelling revealed caseous yellowish tissue and destruction of the medial end of the second right rib. Suspicion of a tuberculous lesion was raised. The histological report was as follows: "No evidence of tuberculosis, but the picture is obscured by very pyogenic inflammatory changes. Examination of her sputum showed no tubercle bacilli."

On Feb. 12, 1947, she developed pain in the right chest and the external swelling became larger without fluctuation. She was again admitted, and a further radiological examination revealed destruction of the anterior end of the second rib and of the sternum and also general loss of translucency of the right lung without mediastinal shift, the left lung was normal. Bacteriological investigations of the aspirated pleural fluid, which was greenish yellow, showed only scanty mononuclear cells, and the culture was sterile. There was a leucocytosis of 29,600 with 91% polymorphs. A diagnosis of acute osteomyelitis was considered. A biopsy of the rib was taken, and the pathologist reported: "Section shows very severe pyogenic inflammatory changes, there is no evidence of tuberculosis or of a neoplasm in the material submitted." There was no response to a course of penicillin treatment.

The patient was then referred to me for an opinion about the advisability of x-ray treatment. Reviewing the case with the pathologist, he reported further on the slide, as follows: "At first sight the histological appearances suggest a subacute pyogenic inflammatory lesion, with an unusual predominance of eosinophils, but closer inspection reveals large numbers of reticulum cells, often multinucleate of Dorothy Reed type. The appearances are those of Hodgkin's disease partly obscured by gross superimposed pyogenic infection. At the end of March, 1947, an enlargement of a gland in the left axilla was noticed, and its biopsy section showed all the classical features of Hodgkin's disease at an active and relatively early stage of development. Later, enlargement of other glandular areas of discrete nature developed, giving the characteristic appearances clinically."

This case illustrates the value of enlargement of sternal nodes in the diagnosis of Hodgkin's disease. The striking feature in this particular case is the early appearance of this sign, indeed it was the only abnormal physical sign at the time of the first examination.

I wish to thank Mr H. Morton Anderson and Dr W. C. MacCWilson for their co-operation in this case.

## Reviews

### ENDOCRINOLOGY

*Textbook of Endocrinology* By Hans Selye, M.D., Ph.D., D.Sc., F.R.S. (Canada) With a preface by Professor B. A. Houssay (Pp 914 illustrated \$10.24) Montreal Acta Endocrinologica, Université de Montréal

In a tribute prefacing this important book Professor Houssay writes "This book represents a critical and concise, orderly presentation of what is most important in the immense collection of facts of modern endocrinology, a science so vast that there are specialists in numerous branch problems and few who know this entire field of study", and "the limitations of space [actually 868 pages] oblige him to be somewhat dogmatic in his exposition". Selye, in his introduction, writes that his book represents a miniature of an 'encyclopaedia of endocrinology' that is being prepared for publication and for the basis of which some 250,000 articles and books have been collected.

The first chapter, on the steroids, is a fascinating physico-chemical introduction to the science of endocrinology made relatively intelligible to the uninitiated by symbolic figures and diagrams. The theme is an appropriate bridge into the next chapter on the adrenals with their multiple secretion of vital steroids by the cortex. The author discusses fully the glycogen corticoids (corticosterone group) and enumerates four tests for gluco-corticoid activity. His account of the pituitary adrenocorticotrophic hormone is perhaps inadequate in view of many interesting papers that were presented at the 1947 meeting at Atlantic City of the Association for the Study of Internal Secretions. Of acute Addison's disease he writes that "death may occur with epileptiform or angina-pectoris-like symptoms"—a rather uncharacteristic description, as might be said of what he calls the chronic nervous or solar type of chronic Addison's disease in which melancholia or spells of acute delirium with maniacal excitement occur. These statements are not untrue but an urge for classification and sub-classification somewhat obscures the clinical background and phase upon which such features may be superimposed. In his account of the physiology of the posterior pituitary he might have said more about the important work of Verney and colleagues on the effect of water (or deprivation of it) and salt and of emotion on the secretion of the antidiuretic hormone. A very interesting section—on a topic often neglected—is the one on the effect of extirpating various endocrine glands on the structure of the hypophysis. The remark that Simmonds's disease is about four times more frequent in the female sex is an understatement and does not take into account Sheehan's fundamental work in Glasgow, to which, surprisingly, I could find no reference. The inclusion of Simmonds's disease together with pituitary dwarfism and Frohlich's syndrome in omnibus descriptions of the symptomatology, etc., of anterior-lobe hypofunction has obvious disadvantages. The statement that 'Cushing's disease may be difficult to differentiate from Cushing's syndrome' leaves the reader rather puzzled.

The account (including historical aspects) of the morphology, pharmacology and physiology of the ovaries is refreshingly stimulating and clear. He mentions ovarian agenesis and its description both by Turner and by Albright. There is an imposing classification of ovarian tumours, and he describes some associated clinical pictures. He does not discuss the fundamental work of Scowen on the nature and treatment of metropathia haemorrhagica. The experimental and clinical chapters on the pancreas and parathyroids are well done and among the best in the book but the chapter on hypothyroidism is not adequately illustrated. He briefly mentions the important influence of tracer studies with radioactive iodine on the physiology and pathology of thyroid function. The therapeutic use and limitations of radioactive iodine in carcinoma of the thyroid are indicated but this physico-chemical approach to the cure of thyrotoxicosis does not appear to have caught my eye, nor is there reference to the valuable work of Rawson and colleagues in this field at the Massachusetts General Hospital. A striking and useful chapter on the general-adaptation syndrome ends this remarkable book. To point out certain minor inadequacies or to say that the historical experimental and

physiological sections are more satisfying than the clinical, is no detractor from a splendid achievement in the complex and rapidly changing field of endocrinology, for which we are fundamentally indebted to Selye.

S. LEONARD SIMPSON

### THE MENTALLY UNBALANCED

*Le Déséquilibre Psychique Ses psychoses—sa morale* By Dr J. Borel (Pp 380 360 francs) Paris Presses Universitaires de France 1947

The subject of this monograph, the 'mentally unbalanced' is one of the wide clinical concepts for which French psychiatry has shown a preference since the last century. It comprises a large group of constitutional mental abnormalities ranging from the mild eccentricity sometimes seen in artists to severe forms of antisocial psychopathy, drug addiction, and alcoholism. Borel sees transitions everywhere and so many mixtures of symptoms that he does not even attempt to discriminate and form distinct groups. The book is mainly descriptive and its strength is the lively and clear portrayal of people suffering from all types of personality deviation. He compares their differences with the individual variations among normal human beings and mainly blames heredity for their abnormal conduct.

In the first part he discusses the mentally unbalanced person describing his mental make-up in terms of the common-sense psychology unfortunately so often used in clinical psychiatry, which prevents the development of more precise and scientific discussion of the psychology of the abnormal. In the second part he draws attention to certain psychotic reactions characteristic of and modified by the unbalanced nature of the underlying personality. In the last part, on the patients' morale he describes and discusses criminal propensities and especially sexual perversions due to lack of psychological balance. Final remarks on the legal responsibility of the mentally unbalanced are inspired by the same philosophical attitude of the wise and experienced clinician which distinguishes the work as a whole.

### DYING AND RESUSCITATION

*Dying Apparent Death and Resuscitation* By S. Jellinek, M.D. (Pp 263 10s 6d) London Baillière, Tindall and Cox 1947

This book is written in a discursive style which is seldom found in modern scientific works. In parts this contributes towards interest and readability, but it tends also to obscure the fundamental points which are considered to be at issue. The author has obviously studied his subject deeply and read widely. One of the results is that we are given momentary glimpses of the death beds of Rabelais, Goethe, Verdi, Napoleon, Seneca and others, and are reminded of the comments of Homer, Cicero, Tacitus, and our own Will Shakespeare. These are all very interesting, but one is left wondering whether the author is explaining these historical and even legendary references in terms of his own beliefs or whether he is advancing them as evidence of the validity of these beliefs. We are not likely to be increasingly alarmed by the knowledge that Chopin stipulated that in the event of his (apparent) death he should be subjected to "the heart incision" before being consigned to the tomb, and surely it is inaccurate to suggest, as the author does that at the present time there are many doctors who make the same stipulation.

Professor Jellinek does well to remind us that we should ponder over the origin of the process of dying as distinct from the commonly accepted causes of death. But it hardly seems necessary to make a mystery of why people with heart disease die suddenly while engaged in heavy work. It would seem that the 'originator' is as apparent in such cases as in those of biophysical and biochemical origin which he instances. And again, why must it be accepted that a sudden collapse after an injection of eucaine (benzamine hydrochloride, dose unspecified) is of psychical origin or due to the pain of acupuncture? In discussing the 'scope and potentialities of the psychicum in the dying process' the author tends to become metaphysical. When he says that in the death agony "the life-principle and the indwelling tension (potentiality) in each separate cell seek to maintain themselves," that may or may not be intelligible to physiologists. But what are we to make of the contention that the very fact that it is movements of the emotions which are

of ethical significance—the worlds of ethics and of energy are entirely foreign to one another—which fill up the content of consciousness and lend to the clinical emotional phenomenon (the intra-rational interval) its peculiar stamp, will hardly permit of the assumption that the course and starting point of this emotional activity is to be sought in the physical sphere, i.e. in energetic processes of the nerve cells. Professor Jellinek wishes to tell us I think that on earth, as in heaven, there are more things than are commonly dreamed of in our everyday medical philosophy.

The second part of the book is a review of present day life saving procedures and indications for their improvement, which the author considers is much needed. In particular he stresses the dangers which attend the elimination of intrathoracic negative pressure by unnatural compression of the chest and, conversely the beneficial effects on the circulation of methods which more successfully simulate the natural variations of pressure within the thorax. It is strange, therefore, to find no reference in the book to Eve's rocking method of artificial respiration which appears to meet the requirements of the author more closely than any of the other methods described. Professor Jellinek concludes with a plea for a national centre for life saving information and technique through which the subject might be taught more widely, more thoroughly, and with greater emphasis on the practical problems involved.

SYDNEY SMITH

### DEVELOPMENT OF SCIENCE

*An Outline of the Development of Science* By Mansel Davies  
The Thinker's Library No. 120 (Pp 214 illustrated 3s 6d)  
London: Watts and Co. 1948

The author of this agreeable little book is a physical chemist, but he has not yielded to the temptation to give much more space to the wonders of physical and chemical science than to the less spectacular history of the biological sciences. His book is admirably written, and could, I think, be read with pleasure by any intelligent person. The two or three pages devoted to modern bacteriology and immunology are a model of accurate summarization although some may doubt whether, as a bacteriologist, Koch was second to Pasteur. Dr Davies quotes Bertrand Russell's sneer that Newton "was honoured by monarchs and in true English spirit was rewarded for his work by a Government post in which it could not be continued. Even Governments deserve fair play: it seems quite certain that Newton ardently desired the post which he was given and very doubtful whether even a modern police State could have forced him to go on doing work which he for psychological reasons no longer wished to do.

MAJOR GREENWOOD

In *A Handbook for Nursery Nurses* by Mrs A. B. Meering, SRN (Brilliance Tindall and Cox, 17s 6d) there has been added for the first time into one book a reasonably complete account of all that a pupil nursery nurse needs to study. Mrs Meering, writing from her wide experience of nursery work, approaches the subject of training in child care from the practical side and seldom forgets that she is writing for young girls the majority of whom will not have had a vestige of scientific training. In the earlier days of nursery work most of the emphasis was on the physical care of the child and provided he was well fed, was kept clean and tidy, and put on weight it was thought that little more was needed. In recent years the pendulum has tended to swing in the opposite direction and the fascinating study of the growth of the child's mind and character has sometimes obscured the study of the care and protection of his very susceptible body. Mrs Meering holds the balance fairly between these two points of view, and the student who is guided by her book will make a good start towards learning to watch and care for a child as a whole personality—growing in mind and body. Her chapters on mental growth, play and child management would be helpful to mothers as well as to students and to not a few nurses and doctors. Some chapters—for example those on anatomy—are perhaps more detailed than necessary but they are useful for reference. On the other hand, the section on the cause of infection and its prevention might well be amplified. The subject is difficult to teach to the uninitiated, but it should be possible to make more use of the descriptions of nursery technique as a means of illustrating the methods of preventing infection since practically the whole of nursery hygiene has its basis in the ubiquity and troublesome habits of pathogenic organisms. However, this is a sound book even though as Prof. Moncreff says in his foreword one may disagree with the author on some points of detail.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Fractures and Orthopaedic Surgery for Nurses and Masses* By A. Naylor, Ch M., M.B., M.Sc., F.R.C.S. F.R.C.S. Ed. 2nd ed (Pp 296 17s 6d) Edinburgh: E and S Livingstone 1948

This edition contains new material on the use of penicillin.

*The Driving Forces of Human Nature* By T. V. Moore Ph.D., M.D. (Pp 461 \$6 50) New York: Grunc and Stratton 1948

An introduction to the psychology of normal and abnormal emotional behaviour and volitional control.

*Practical Bacteriology, Hematology, and Parasitology* By E. R. Stitt, M.D., Ph.M., Sc.D., LL.D., and others 10th ed (Pp 991 50s) London: H. K. Lewis 1948

A textbook for the medical practitioner.

*Textbook of Genito-Urinary Surgery* Edited by H. P. Winsbury, White, M.B., Ch.B., F.R.C.S. (Pp 1,046 90s) Edinburgh: E and S Livingstone 1948

An illustrated textbook including operative details.

*Post-Mortem Appearances* By J. M. Ross, M.D., B.S., M.R.C.S., L.R.C.P. 5th ed (Pp 308 8s 6d) London: Geoffrey Cumberlege 1948

A short account for students and practitioners.

*Recent Advances in Therapeutics* By J. R. Goyal, M.B., B.S. 3rd ed (Pp 288 Rs 7 8) Delhi: Yugantar Press 1948

A practical summary of recent advances.

*Vision and the Eye* By M. H. Pirenne, D.Sc., Ph.D. (Pp 187 12s 6d) London: Pilot Press 1948

A short account of the structure and function of the eyes including discussion of colour vision.

*Handbook of Medicine for Final Year Students* By G. I. Walker, M.D., M.R.C.P. 4th ed (Pp 305 25s) London: Sylvio Publications 1948

*A Short Practice of Surgery* By Hamilton Bailey, F.R.C.S., F.A.C.S., F.I.C.S., F.R.S. Ed., and R. J. McNeill Love, M.S., F.R.C.S., F.A.C.S., F.I.C.S. 8th ed Part II (Pp 420 Complete set 52s 6d) London: H. K. Lewis 1948

This part is on the surgery of the alimentary system.

*On Life and Sex* By Havelock Ellis (Pp 282 17s 6d) London: Wm Heinemann 1948

Essays on the problems of sex in society.

*Therapeutic Social Clubs* Edited by J. Bicer, M.D. (Pp 71 6s) London: H. K. Lewis 1948

Articles by various authors on clubs for psychotic and neurotic patients, for the mentally defective, and for difficult children.

*Educational Sociology* By F. J. Brown (Pp 626 21s) London: Technical Press 1948

A textbook of the sociology and psychology of education.

*Proteins and Life* By M. V. Tracey, M.A. (Pp 154 10s 6d) London: Pilot Press 1948

An account of the structure and functions of proteins for the general reader.

*A B C's of Sulfonamide and Antibiotic Therapy* By P. H. Long, M.D., F.R.C.P. (Pp 231 17s 6d) London: W. B. Saunders 1948

A concise summary of the use of sulphonamides and antibiotics.

*New Biology* Edited by M. L. Johnson and M. Abercrombie (Pp 130 1s 6d) London: Penguin 1948

Articles for the non specialist on recent biological advances.

*Nursing Arts* By M. L. Monting, A.M., R.N., and M. Fife, A.M., R.N. (Pp 603 17s 6d) London: W. B. Saunders 1948

An introduction to nursing for students.

## CHEMOTHERAPY OF CANCER

From the work of Fildes and Woods in 1940 emerged the "rational approach" to chemotherapy. The administration of the sulphonamides starves susceptible bacteria of *p*-aminobenzoic acid, which is essential to their metabolism, from this it was an easy step to suggest that analogues of known bacterial growth factors or essential metabolites should prevent or slow down the growth of micro-organisms and might prove to be of considerable value as chemotherapeutic agents. Several hundred analogues of compounds known to be of importance to the cell have now been synthesized, and many of them interfere with the growth of bacteria *in vitro*. To give one example vitamin K, 2-methyl-1,4-naphthoquinone, is an essential growth factor for certain fungi such as *Fusarium solani*. An active fungicide, 2-methoxy-1,4-naphthoquinone, was obtained from *Impatiens balsamina* by Little and his colleagues.<sup>1</sup> Its fungicidal action is due to the fact that it is a competitive inhibitor of vitamin K. Similar competition occurs between vitamin K and 2-chloro-1,4-naphthoquinone, the latter compound also acting as a fungicide.<sup>2</sup>

Many of the analogues which are active *in vitro*, however, are inactive *in vivo* or are too toxic to the host to be considered as possible chemotherapeutic agents. Only certain analogues of pantothenic acid, which is essential for the growth of some bacteria and the malarial plasmodia, retain the capacity to inhibit the growth of the same micro-organisms *in vivo* and at the same time fulfil the other requirements of a chemotherapeutic drug. Had not other antimalarial drugs such as chloroquine and "paludrine" been discovered during the war years it is probable that phenylpantothenone would be regarded as a considerable practical achievement for the "rational approach". Nevertheless, Sir Paul Fildes,<sup>3</sup> in opening a discussion at the Royal Society in June, expressed disappointment that this approach had yielded nothing of immediate chemotherapeutic value. This failure was attributed partly to the fact that the metabolic patterns of host and parasite were often so similar that an agent which interferes with a given process in one cell is only too likely to interfere with the metabolism of another cell, independent of species. The repetition of metabolic patterns is strikingly shown in the group of vitamins which make up the B complex. Members of this group have an extremely wide distribution as

essential metabolites and are necessary for the nutrition of organisms as dissimilar as man and virus. Although analogues of the B vitamins have been synthesized in considerable numbers they have not found a place in chemotherapy because they interfere with the same fundamental processes in both parasite and host. Only *p*-aminobenzoic acid has been used clinically for its chemotherapeutic effect: its action on pathogenic rickettsiae was discovered when it was found that sulphonamides, which are normally inhibited by *p*-aminobenzoic acid, promote the growth of rickettsiae. Analogues such as those of aneurin, nicotinic acid, and folic acid have in fact produced in laboratory animals syndromes indistinguishable from those produced by simple dietary deficiencies.

Despite many failures in the use of these analogues for the treatment of infections a very striking application has now been found for them in the chemotherapy of the Rous sarcoma in chickens. Little and his colleagues<sup>4</sup> showed that by maintaining baby chicks on a diet completely lacking in folic acid (pteroylglutamic acid) the development of the Rous sarcoma could be prevented in 100% of them, and in 40% of six-weeks-old birds. On the other hand, N-methyl folic acid, pteroyldiglutamic acid, and pteroyltriglutamic acid can all replace folic acid, since the growth of tumours is not prevented in birds fed on a diet free from folic acid and then injected with any of these compounds. If, however, folic acid was injected with *d*(-)-glutamic acid, pteroylaspartic acid, pteronic acid, N-methylpteronic acid, or PAB-triglutamic acid no tumours developed since these compounds were unable to replace folic acid. The next step was to feed chickens on an ordinary mixed diet and to determine the effect on the development of the Rous sarcoma of known analogues of folic acid. When injected into chickens in doses of 200 or 400 µg per day 4-amino-pteroylaspartic acid was found to reduce the number of chickens developing tumours by 60%. When 4-amino-folic acid with *d*(-)-glutamic acid was used in a dose of 400 µg per day results were even more striking, for the development of all tumours was prevented, with a daily dose of 200 µg only half the birds developed tumours.

These findings are of very considerable interest. It is now four years since Leuchtenberger and his colleagues<sup>5</sup> first claimed that pteroyltriglutamic acid, the original *Lactobacillus casei* factor, inhibited the growth of sarcoma 180 transplanted in female mice. In later publications<sup>6</sup> they showed that folic acid itself had no therapeutic effect on spontaneous breast tumours in mice, whereas the fermentation *L. casei* factor caused complete regression in 30-40% of tumours.

These findings served as an impetus to the synthesis and to the clinical use of pteroyltriglutamic acid, now referred to as teropterin. This is a yellow powder, freely soluble in normal saline, apparently stable at room temperature, and completely painless on injection. No toxic effects have been observed in animals. More than 100 cases of malignant growths in man have been treated with this drug in Boston, and details of 20 patients who have received the drug in New York have now been reported by Lehr and his colleagues.<sup>7</sup> These patients, in an advanced state of the disease, have been under treatment for one to three

<sup>9</sup> *ibid.* 1948, 10, 99.

months. In the majority of cases pain was relieved, and the patients became more cheerful and mentally alert. Some put on weight and have returned to work. Klammer<sup>8</sup> reports a striking improvement in a female patient with metastases in the spine secondary to a breast tumour which had been removed. She was given 150 mg of testosterone propionate daily in three divided doses and 60 mg of terofterin, each drug being injected intramuscularly. After nine months, still on terofterin, the patient was completely ambulatory. Radiographs of the spine showed regeneration of bone in the involved areas, and her only complaint was of mild aching in the lumbar spine after prolonged walking or standing. How far improvement was due to terofterin and how far to testosterone cannot yet be judged.

Terofterin has also been used by Meyer<sup>3</sup> in the treatment of leukaemia. In chronic lymphatic leukaemia no striking changes occurred with doses up to 200 mg a day. Subjective improvement was seen in two patients with myelomatosis, but no changes were found in the bone marrow. In cases of acute lymphoblastic leukaemia both terofterin and pteroyldiglutamic acid have reduced the white cell count. Improvement has also been observed in patients with acute myelogenous leukaemia treated with N-[4-[(2-amino-4-hydroxy-6-pteridyl)methyl]amino]-benzoyl]dl-aspartic acid or 4-(-N[(2-amino-4-hydroxy-6-pteridyl)methyl]-N-methylamino)benzoic acid. Both these compounds are said to act as folic acid antagonists. While no claim can be made that the rational approach to chemotherapy has yet provided a cure for human malignant disease, folic acid antagonists form a group of compounds which will well repay further intensive investigation.

## VITAMIN C

The daily amount of vitamin C required by man for health, the earliest clinical signs of deficiency, and the effects of a deficiency upon the healing of wounds are questions which a recent large-scale experiment was designed to answer. The results are contained in the preliminary report<sup>1</sup> of the Vitamin C Subcommittee of the Accessory Food Factors Committee of the Medical Research Council. The experiment, which continued for eighteen months, was carried out at the Sorby Research Institute of the University of Sheffield under the supervision of Professor H. A. Krebs. Twenty volunteers took part and between them submitted to 72 wounds. The experiment was a "blind" one in that neither observed nor observer was allowed to know whether any particular individual was deprived or protected—an essential requirement when clinical features are to be assessed. The diet was designed to be complete, well balanced, and relatively palatable, but it contained less than 1 mg of irremovable vitamin C. This vitamin was provided in tablet form, and after a preliminary period of saturation (70 mg per day for six weeks) dummy tablets identical in size, shape and taste were substituted. Three control subjects continued to receive 70 mg per day, seven received 10 mg per day, whilst the 10 remaining were completely deprived of the vitamin apart from the irremovable milligramme (or less). All these 10 developed symptoms of scurvy. Four of those

in the group restricted to 10 mg per day remained normal during the whole period (424 days in three cases and 252 in the fourth). In the three others there were no signs of scurvy after 160 days, and they were then totally deprived of the vitamin in order to find out whether the period of low intake had rendered them more susceptible. In two of these three a period of total deprivation for 71 days produced at most doubtful initial lesions (slight hyperkeratosis).

In order to determine the minimum effective curative dose six of the totally deprived who had developed clinical scurvy were given 10 mg of vitamin C per day, they steadily improved upon this very small dose. Some tests for physical fatigue, though not conclusive, showed small differences in favour of the group receiving 70 mg compared with those on 10 mg per day. There are thus good reasons for supposing that 10–11 mg is the minimum daily requirement for the human adult, but the subcommittee considered that it would not be unreasonable to recommend 30 mg as the daily requirement, since a margin of safety must be allowed for additional needs as yet very ill-defined. It is, however, obvious that intakes much less than this are not necessarily detrimental to health. The U.S. National Research Council's<sup>2</sup> figure of 75 mg was based upon saturation experiments and theoretical considerations, and there is no evidence to show that it has any advantage over 30 mg, which was the amount recommended by the League of Nations Technical Commission on Nutrition.<sup>3</sup>

When the records of the experiment were reviewed the earliest clinical sign of deficiency was found to be hyperkeratosis of the hair follicles. It occurred after 17–21 weeks, but it is not diagnostic of scurvy. The perifollicular haemorrhages which followed (at 26–34 weeks) are almost diagnostic. Swelling and haemorrhages of the gums appeared later (30–38 weeks) and less constantly, this seems to indicate that oral lesions should not be diagnosed as scurvy in the absence of skin lesions, unless hard ship's biscuit happened to be the main item of food. An interesting sign was a striking exacerbation of previously existing acne, this was noticed after 22 weeks. The volunteers were intelligent, fully co-operative, and under skilled psychiatric observation, yet it proved impossible to differentiate the deprived from the protected by subjective symptoms or psychological abnormalities. Tests specially designed to detect the apathy which is alleged to accompany scurvy gave negative results. There were no complaints of general pains or weakness. There is thus no experimental basis for the treatment of vague subjective symptoms by vitamin C.

Much biochemical information was acquired. The vitamin-C content of the blood plasma in the totally deprived group and also in those limited to 10 mg of the vitamin per day fell rapidly, but it proved practically impossible to decide from a single plasma test whether any particular individual was upon a fully protecting dose of 10 mg or totally deprived of the vitamin and either suffering from scurvy or in imminent danger of developing it. The estimation of vitamin C in the white corpuscles proved to be

<sup>1</sup> *Lancet* 1948 1 853

<sup>2</sup> *Repr. nat. Res. Coun. Wash.* 1943 No. 122

<sup>3</sup> *Quart. Bull. Hlth. Org. L.N.* 1938 7 461

a more sensitive test, and there is hope that improvements in technique may make it possible to estimate accurately the vitamin C deficiency in any individual. At present, however, the test can be used only to exclude the diagnosis of scurvy. No abnormalities were observed in the capillary filtration rate, in the body weight, in the incidence of minor infections, in the appearance of the capillaries of the nail bed and of the conjunctivae, and in the dark-adaptation of vision. There were no haemorrhages apart from those in the skin or gums. The "cuff" tests for capillary fragility gave no consistent results. Haemoglobin estimations and erythrocyte and leucocyte counts, including differential counts, were normal and thus gave no support for the theory that vitamin C is a necessary factor in haematopoiesis. Platelets, bleeding time, plasma protein, albumin globulin ratio, blood urea, and phosphatase were all normal.

These hard facts will disprove some of the suggestions which have been made about the clinical and pathological signs of vitamin-C deficiency, but they will not obscure the fact that scurvy can be a dangerous condition. Three out of ten of the deprived subjects developed serious symptoms. The most severely affected of these suffered an exacerbation of a previously existing but symptomatically latent tuberculous spondylitis, another had an acute cardiac emergency with an ECG suggestive of coronary thrombosis, whilst the third had praecordial pain associated with heart-block (partial) not discovered in a previous ECG. All had recognizable scurvy at the time of the breakdown. The effects of vitamin-C deprivation on wound healing are more difficult to assess from the report, and it is to be hoped that fuller details will be published. The old observation that scars become red and livid was confirmed. It was established that when clinical signs of scurvy were present wounds often showed defects of healing, but in one individual suffering from scurvy a wound healed normally. In the group of subjects taking 10 mg of the vitamin per day no defects of wound healing were seen.

It would be almost impossible in this country to provide throughout the year enough vitamin C to meet the recommended American daily requirement of 75 mg, and it is satisfactory that the subcommittee found that such a large amount was not necessary for health. It is extremely improbable that any individual living in this country on the present rations can be in danger from vitamin-C deprivation. The available supplies of the vitamin can be best used by treating vigorously the real cases of scurvy so as to obtain rapid recovery, they should not be frittered away in treating a multitude of indefinite symptoms classified as 'preclinical' scurvy. It is significant that the clinical observers were seriously concerned about the condition of at least one of the volunteers during the acute cardiac emergency which followed a few hours after an agility test. It seems clear that any patient diagnosed as suffering from scurvy should be admitted to hospital and saturated with ascorbic acid as soon as possible. Some physicians might feel inclined to try out the curative effect of small doses in order to confirm the findings of this report but such an experiment should be undertaken only with a full sense of the responsibility incurred, for liability

to sudden death during the course of the disease was formerly well recognized. When the full report is published it will undoubtedly be a unique contribution to the literature on the subject, and the M R C is to be congratulated on providing the organization and funds which made the research possible.

## SURGICAL TREATMENT OF MENIERE'S DISEASE

Perhaps only those who have suffered from severe attacks of vertigo can realize their devastating effects, social and economic. Ménière's disease is probably the commonest cause of this disability, and treatment is within the province of both physicians and surgeons. Physicians claim that medical treatment can effect a cure, but whether this treatment takes the form of limitation of intake of water or of salt, of injections of antihistamine substances, or of the administration of drugs the results are by no means permanent and some are not appreciated by the patient. Surgeons have therefore applied themselves to the problem. In view of Charcot's statement in 1874 that vertigo ceased when deafness became absolute it appeared that section of the eighth nerve should cure the vertigo, and this was suggested by Ballance in 1894 and performed by Frazier<sup>1</sup> in 1904.

Since this date neurosurgeons have developed the operation of intracranial section of the nerve. In 1933 Dandy<sup>2</sup> described the results of section of the vestibular portion without division of the cochlear nerve, this cured the vertigo and left the hearing unaffected. This operation was adopted by many neurosurgeons with very good results, though it is not without risk to life. Ray<sup>3</sup> has recently advised section of the whole nerve, since he found that even if a few fibres of the vestibular portion are overlooked vertigo can persist. As most patients are deaf before operation, he believes that the subsequent complete deafness does not disturb them.

Otolologists have devised operations to deal with the labyrinth itself, directly or indirectly. Long before Hallpike<sup>4</sup> demonstrated dilatation of the endolymph system in cases of Ménière's disease this condition was suspected, and operations were performed to diminish pressure in the internal ear. The earliest was lumbar puncture, and later drainage of the pontine cisterna was undertaken. In 1927 Portmann<sup>5</sup> opened the saccus endolymphaticus, and this gave successful results in a considerable proportion of cases. Direct drainage by opening the external semicircular canal was performed by Hautant, this procedure, combined with injection of absolute alcohol to destroy the function of the labyrinth, was advocated by Mollison<sup>6</sup>. Injection of alcohol through the footplate of the stapes was devised by Wright. All these operations had the disadvantage of destroying hearing. Later Cawthorne<sup>7</sup> opened the external canal by a specialized technique and removed the membranous canal, this cures the vertigo without affecting the hearing.

In a paper appearing elsewhere in this issue Mr E R Garnett Passe and Dr J S Seymour approach the problem from a different standpoint. They put forward a vascular cause to explain the hydrops of the labyrinth, and suggest that differences in the blood supply to different parts of the internal ear may well account for the relative differences between deafness and vertigo, in some cases vertigo is the important symptom, in others deafness. Since the vertebral

artery supplies the internal ear, they approach the vessel through the subclavian triangle, and after dividing or stripping it they excise the stellate ganglion. Of the 12 cases operated upon all were relieved of vertigo, in all but one hearing was improved, and in nine the tinnitus was modified or relieved. This is only a small number from which to draw final conclusions, but the results are encouraging.

### TREATMENT OF ACTINOMYCOSIS

The treatment of actinomycosis, as of many bacterial infections, has twice been improved in recent years. Whatever view may be taken about the action of iodine in this disease it is generally conceded that the sulphonamides have a more pronounced and dependable effect. Penicillin proved to be even more efficacious and often actually curative. Decker<sup>1</sup> reviewed the earlier results of penicillin treatment and also discussed other forms of treatment. He described three cases typifying his own past experience with this disease: one was cured with penicillin, one uncured by iodine, and one was not diagnosed until the post-mortem examination. It seems probable that cases of actinomycosis still remain undiagnosed or are recognized at so late a stage as greatly to reduce the chances of successful treatment. Both the clinician and bacteriologist should never lose sight of the possibility of this infection in connexion with lesions of the jaw, ileo caecal region, and particularly of the lung, pleura, and chest wall. It is in the thorax that the disease is likely to extend furthest without recognition.

Although the anaerobic *Actinomyces* usually responsible for human infections has been recognized as penicillin-sensitive for some years, there is evidence that the degree of sensitivity varies and that this may affect the results of treatment. Owing to the slow growth of the organism and the difficulty of preparing a standard inoculum estimations of sensitivity can only be approximate, and all existing information on this subject requires review in the light of Holms<sup>2</sup> studies, which are the most thorough hitherto made. He worked with 29 strains derived from 27 patients and determined their sensitivity to penicillin by cultivation in a liquid medium containing falling concentrations of the drug, controlling the test with an identical series inoculated with a standard staphylococcus. The inoculum used was of two kinds, either a suspension obtained by crushing a colony between two sterile slides or a whole colony. When suspensions were used, all the strains were found to have approximately the same sensitivity as the control staphylococcus. On the other hand, entire colonies of the majority of the strains were able to grow in considerably higher concentrations of penicillin—3 of them in 1 unit per ml, the highest concentration tested. By using colonies of different ages Holm demonstrated that resistance varied with colony size. Comparative tests with whole colonies and suspensions equivalent in quantity showed that this was due not just to the bulk of the inoculum, since the suspensions were more readily inhibited. This difference in result according to the dispersion of the inoculum was observed in a group of 20 typical strains. A smaller group differing in morphology, colonial characters, and in being CO<sub>2</sub>-sensitive did not behave in the same way. As Holm points out, the response of the disease to treatment will depend on the capacity of penicillin to attack the organism in the form in which it exists in the lesions, and a sensitivity test using whole colonies as the inoculum is therefore the better guide. The fairly high degree of resistance of some strains when tested in this way may be the explanation for the lack of response

to penicillin in some cases. Patients infected with these strains require a larger dose for a longer time. Perhaps the only safe policy is to give large doses in all cases of actinomycosis unless or until the strain of *Actinomyces* can be examined by Holm's technique, a procedure calling for both time and skill. Thus to discuss the uses of chemotherapy in this disease is not to imply that it can replace surgery: drainage is essential, and excision, if feasible, is perhaps the most valuable measure of all.

### JET INJECTION

A new method of injecting drugs without either syringe or needle is based on the fact that an extremely fine high pressure jet of liquid can pierce the skin without producing pain. Hingson and Hughes<sup>3</sup> have described the apparatus required. The material for injection is contained in a small sterile metal ampoule shaped like a blunt-nosed bullet, with a hole about three-thousandths of an inch in diameter in its end. The ampoule, which is encased in an aluminium container to avoid contamination, is locked in the front of the instrument. This is shaped like the case of a large electric torch and contains a calibrated high tension spring controlled by a release button. When the spring is released it propels a plunger against the metal ampoule, from which liquid is forced through the minute opening as a fine high velocity jet under pressures varying from 2,300–3,500 lb per sq in (1,000–1,600 kg per 6.45 cm<sup>2</sup>). The injection is given by placing the blunt nose of the metal ampoule against the skin, which is stretched taut, and then releasing the spring. The jet which is forced out passes through the skin to a depth of 0.2–2 cm according to the site of injection and the texture of the patient's skin and tissues.

The advantages claimed for jet injection are complete freedom from pain in most patients and a considerable saving of time, since the ampoules are supplied already sterilized. There is obviously a use for such a device in clinics where many injections are given, as in immunization clinics, and perhaps diabetics and those receiving penicillin or streptomycin injections several times a day would prefer it to the hypodermic needle. Jet injection, however, has its drawbacks. If the skin is wet, or if the nose of the ampoule is not in close contact with it, or is tilted, the injection produces a cut and sometimes a blister. It cannot be used for carefully placed injections or for the injection of oily liquids. It is also possible that nerves and blood vessels near the skin might be injured by a high pressure jet. Perhaps the greatest drawback at present is the cost of the apparatus. Jet injection is, however, the first basic change in injection technique for nearly a hundred years. It has already been tried out in the USA in VD and tuberculosis clinics for the routine injection of penicillin and streptomycin.<sup>2,3</sup>

The Thomas Vicary Lecture entitled "The Portraiture of William Harvey" will be delivered by Mr Geoffrey Keynes before the Royal College of Surgeons of England (Lincoln's Inn Fields, London, WC) on Wednesday Nov 17, at 5 p.m.

The Mitchell Lecture will be delivered by Dr Robert Coope, FRCP, before the Royal College of Physicians of London (Pall Mall East, SW) on Thursday, Nov 18, at 5 p.m. His subject is "Tuberculous Enlargement of Intrathoracic Lymph Nodes and its Aftermath".

## STREPTOMYCIN

## THE PRESENT POSITION

A meeting of the Medical Society of London was held on Oct 25 for a discussion on streptomycin. Dr JENNER HOSKIN presided.

Dr JACK RUBIE gave a brief account of the treatment at Highgate Hospital by means of streptomycin of a group of cases of children with tuberculous meningitis. The scheme of treatment was as follows:

	Days
Intramuscular and intrathecal injection	28
Intramuscular only	28
Intramuscular and intrathecal	28
Rest	28
Intramuscular only	28
Followed by observation for two months or more, with further treatment if symptoms reappeared	

The daily dose intrathecally was 0.1 g in 10 ml solution, and intramuscularly 0.02 g per lb body weight. Some of the cases under treatment showed symptoms such as fever, anorexia, vomiting and skin rashes, but these, if at all severe and prolonged, were considered more likely to be due to the disease than to the drug. Two types of skin lesion were encountered: an urticarial eruption and an exfoliative dermatitis. The latter responded remarkably well to a local application of cod-liver oil. Ten of the cases were operated on to relieve hydrocephalus. It was difficult to give the indications for this operation, but so far it had been performed when there was a suggestion of relapse with headache, vomiting, and papilloedema. The puncture was made to approach the descending horn of the lateral ventricle, and a tube was inserted into the ventricle and allowed to drain. This was carried out as a prophylactic measure in children under 3. The lumbar puncture was continued for the streptomycin administration, and the operation used only for the purpose of mechanical drainage.

In a small number of cases sulphathione had been added to the streptomycin. This was given only intrathecally, and its diffusion into the blood by that route gave almost as high a blood level as by the intramuscular route. This drug was toxic at anything above the blood level of 10 or 12 mg per 100 ml. One case which had received this combined treatment had a normal cerebrospinal fluid 100 days from starting treatment, and a second case appeared to be doing well. In nursing these patients it was important, especially with those under 3 years of age, that they should not lie supine for long periods. The children were made to sit up and were kept on the move, and thus exudate was prevented from forming as a solid plaque in the posterior fossa.

Of 58 patients 22 had survived more than 120 days and 20 were doing well. Out of this number 44 had had the combined intramuscular and intrathecal treatment, and of these 19 were alive after 120 days and 17 were doing well. 10 had had intramuscular treatment alone, and among these there were only two survivors, and four others started with intramuscular treatment but when it was realized that this was not proving efficacious they were switched over to intrathecal treatment, and of these only one survived. He emphasized the improved results in early cases: out of 17 cases in which treatment was begun early 11 had survived. Dr Rubie showed photographs of a number of these children to all appearances normal who, he said, had been under observation for varying periods up to sixteen months. 12 of them now had a normal cerebrospinal fluid.

## Pulmonary Tuberculosis

Dr GEOFFREY MARSHALL referred to the Medical Research Council committee which was set up two years ago. [The committee's report appeared in full in the *British Medical Journal* of Oct 20 p 769.] Dr Marshall said that tuberculosis presented itself most obviously as a condition in which the remedy should be tried, because the death rate was so near 100% that any good results in such cases must mean that streptomycin had value as indeed had been proved. On the other hand in tuberculous disease of the lung it was much more difficult to assess the results of treatment, and it

was necessary to have control cases. The 55 patients who received streptomycin were given treatment on what later experience showed to be a rather massive scale—0.5 g of streptomycin four times in twenty-four hours. He believed that 1 g a day was sufficient.

The overriding difficulty in the streptomycin treatment of pulmonary tuberculosis had been the development of resistant strains of tubercle bacilli. This difficulty did not arise in the cases of tuberculous meningitis. If with the development of resistance something like, say, ten times as much streptomycin was required as when treatment first started it might not worry them, but within about six or eight weeks many strains of tubercle bacilli were found in the sputum which called for about a thousand times the original strength of streptomycin. As the strains became more resistant not only was the lessened effect demonstrable bacteriologically, but parallel with it was a decline in the clinical results. The patients were better at the end of three months than they were at the end of six. Some attempt had been made to 'dodge' this effect by altering the rhythm of treatment. During the first month relatively little resistance was found and during the second month much more, so that they thought of giving streptomycin for a month and then desisting for a month. Unfortunately this did not work. During the second month even if the streptomycin was discontinued the resistant strains increased. Perhaps it was better to give streptomycin for six weeks and then end it. It was a valuable remedy, but it must be used with discretion and not in pulmonary tuberculosis unless there was a real indication for it.

Many patients who were bad risks coughing up large numbers of tubercle bacilli, had done so well that it was possible to institute collapse therapy within six months, whereas this had not been advisable at the beginning. Tuberculous ulceration of the bronchi had healed completely under streptomycin, but the difficulty arising from cicatrization remained. A small number of cases of acute miliary tuberculosis had recovered. Toxic reactions took the form of urticaria and other forms of rash, and occasionally there was damage to vestibular function in some cases permanent, and affecting the middle-aged and elderly rather than the young.

## Bact coli Infections

Sir ALEXANDER FLEMING said that under treatment with streptomycin patients with miliary tuberculosis got well for a time but the disease returned. It might not be so great a misfortune that the supply of streptomycin was restricted, when supplies became more abundant, as they would, there might well be misuse and disappointment. Streptomycin had a powerful effect on *Bact coli*. The results within twenty-four hours in some infections were marvellous, but if the infection did not disappear within twenty-four or forty-eight hours the chances were that the *Bact coli* had become resistant. There was either a quick result or no result at all. It was a pity to tinker with the drug, and it was just as well in these *Bact coli* cases to give as big a dose as practicable and kill off the organism. Certain results indicated that given by the mouth streptomycin had a rapid effect in infantile diarrhoea. It was a local action, no big dose need be given. This might turn out to be a very important use for this drug.

Dr JOSEPH SMART said that streptomycin should be used with great care and under certain specified conditions. It was thought that it might be useful to administer by inhalation and placing the drug directly on the larynx, but this had proved disappointing. On the other hand, a tuberculous larynx treated with streptomycin intramuscularly responded very well. Cases of gross ulceration and massive destruction of the main bronchi were relatively rare, but it was quite common to get small superficial ulcers, and under streptomycin treatment such ulcers healed very well.

## Urinary Infections

Mr E. W. RICHES spoke of the use of streptomycin in tuberculous infections of the urinary tract. With the small amounts available it had not been possible to try it extensively. He had used it, however, in a number of cases which he would describe as complicated in the sense that they had some other surgical condition as well as the infection, they were cases

which had undergone prostatectomy or had stricture, and so on. In these cases they had concentrated on organisms which were not responsive to most other drugs, particularly *Ps pyocyanea*. They had given doses of 3 g a day, up to a total of 12 g. *Ps pyocyanea* had disappeared in 14 out of 20 cases, *B proteus* in 4 out of 4, *Bact coli* was not always eliminated. The good results did not mean that the urine was always sterile, because frequently at the end of treatment there were streptomycin-resistant organisms left. He did not think that the results of treatment should be assessed solely on the basis of the bacteriological picture. There had been a number of cases in which the clinical improvement had been most striking. It was not to be expected that a permanent sterilization of the urine would be obtained with streptomycin in the presence of any surgical lesion such as urinary obstruction, or in gross organic disease. The great value of streptomycin urologically was in post-operative or more particularly post-radiation infections. In cases such as carcinoma of the bladder treated with radium a *Ps pyocyanea* or *B proteus* infection might in the ordinary way go on for months, and in such cases streptomycin was of great value. In urinary tuberculosis there had been no proved cases of permanent disappearance of tubercle bacilli from the urine, but a certain amount of clinical improvement had been observed, as shown by increased capacity of the bladder.

Dr W G OAKLEY said that in treating by means of streptomycin diabetic patients with urinary infection it was important to get rid of the sugar before giving the drug. Dr BUTLER described a case of *Bact coli* infection in the urine with synovitis, both of which conditions cleared up under a total of 12 g of streptomycin.

Dr MARSHALL, in reply, said that it was the general experience that little was seen of resistant strains in treating cases of meningitis, but such resistance was almost invariable in pulmonary tuberculosis. To show the value of streptomycin in ulcerative conditions he mentioned the case of a woman who became pregnant. The tuberculosis officer advised termination of pregnancy. The woman belonged to a Church which frowned upon that procedure, and she went from bad to worse. After the birth of the child she developed a severe ulceration of the epiglottis, so that she could not swallow even saliva. A supply of streptomycin was obtained, and within five days of starting treatment she was perfectly comfortable, and within a few weeks the ulceration of the epiglottis had healed.

## THE PRACTITIONER'S PART IN THE ANTI-TUBERCULOSIS SCHEME

### A PLEA FOR PROMPT RADIOGRAPHY

BY

PETER STRADLING, MD, MRCP

Physician in charge of Hammersmith Chest Clinic and Lecturer in Tuberculosis Postgraduate Medical School of London

There is in this country a widespread failure to tackle tuberculosis adequately, and it is the aim of this article to deal shortly with one vital aspect of the problem. Through no fault of his own the general practitioner in particular does not at present fully utilize his unique opportunities of raising the Tuberculosis Service from its present mediocrity to the highly efficient organization that it might and should be. It will be shown that avoidable delay in the diagnosis of pulmonary tuberculosis occurs in the doctor's surgery, and the significance of this will be indicated. The practitioner will then appreciate how indispensable is his co-operation and how best to use his opportunities of attaining early diagnosis.

#### Delay in Diagnosis

It was decided to investigate the histories of a series of cases to determine what period of time constituted the average delay in diagnosis and, if possible to discover where the greatest delay occurred. For this purpose 345 consecutive cases were taken diagnosed in the years 1946 and 1947 and resident in the area

of North-West London administered by Willesden Chest Clinic. Of these cases 297 were referred to the chest clinic for investigation by their own doctors on account of symptoms. Of the 48 cases referred from a mass radiography unit 35 so far have proved inactive and symptomless, and of 13 which proved active 10 had symptoms. The first obvious fact arising from these figures is that 99% of the active cases in this series had symptoms for varying periods of time before attending the chest clinic and could therefore have been diagnosed earlier had action been taken immediately these had begun.

The histories of the patients who had consulted their own doctors (86%) were further analysed to discover (a) the time interval between the first suggestive symptom and first seeking medical advice, (b) the time elapsing after this first consultation before the patient's chest was x-rayed. The intervals in individual cases vary widely but the average figures for the whole series are as follows:

First symptoms to first consultation	17 months
First consultation to diagnostic x ray	40 "
Total	57 "

The immediately striking fact is not only the length of delay but that over two thirds of this delay occurs after the patient has reported symptoms to his doctor. Furthermore it is not only patients with relatively minor symptoms whose disease is missed. In 56% of practitioners' cases in this series there was a delay of over four weeks in spite of the patients reporting haemoptysis, severe chest pain, or cough lasting more than one month.

It is instructive to compare these figures with those given by Mann (1943) for a group of sanatorium patients:

Delay in consulting doctor	3.64 months
Delay before referred for consultation	3.28 "
Total	6.92 "

The difference between the two series of figures is so marked that a conclusion is probably justifiable in spite of their not being strictly comparable (the present figures refer to a chest clinic, Mann's to a sanatorium). The significant fact will immediately be appreciated although the patient's delay in attending a doctor's surgery is markedly less in this series, there has been no similar shortening of the period between the patient's first visit and a diagnosis being attained. It would appear that the general public is becoming more conscious of the significance of pulmonary symptoms and the necessity for x-ray examination, thus throwing into relief the deplorable fact that a similar event is not occurring in the ranks of our own profession.

#### Significance of Delay

Although pulmonary tuberculosis forms our major public health problem to day, the methods for its control are deplorably inadequate. The disease accounts for more deaths in the productively useful age group than any other single factor just at a time when an increase of industrial output is urgently required. It is widely recognized that the earlier in the evolution of the disease treatment is instituted the rosier is the outlook for the individual sufferer, yet the wait for sanatorium admission is in the region of six to nine months. The rise in the tuberculosis death rate in 1947 (*Lancet* 1948) is probably in part a reflection of this fact. What is not so well appreciated is that the majority of dangerous infections start acutely in young adults and may progress very rapidly indeed. Weeks or even days of delay in referring a patient for chest radiology are often of vital significance whilst the months indicated by these figures often mean that the patient is beyond treatment before his name can even be added to the bottom of the sanatorium waiting list.

I believe that the main reason for the failure to utilize even existing facilities for radiology is the widespread misunderstanding of the symptomatology of incipient tuberculosis. Sir James Mackenzie (1923) wrote, 'The defective education of the general practitioner renders him incapable of utilizing his opportunities for the progress of medicine, and I would add that extreme overwork too often exaggerates this position. Unfortunately both textbooks and the propaganda accompanying

the mass miniature-radiograph campaign tend to suggest that insidious onset is the rule, so that the practitioner may even be led to believe that early diagnosis is a Utopian objective

The figures given show that a definite symptomatology is present in practically every active case. Sometimes dramatic but frequently only slight, these symptoms may have to be diligently sought after, and unfortunately they are often suggestive of other less serious illnesses. Such mimicry may lull the practitioner into inactivity while possible suspicions are further dispelled when the patient, after an illness of acute onset appears to recover his former health wholly or in part (a common temporary occurrence). In addition physical signs may be absent or positively misleading. A statement made by Fishberg and quoted by Jessel (1941) is an apt ending to this short review. "There may be active phthisis without physical signs revealing themselves even to the best-trained specialist but there is no active phthisis without constitutional symptoms."

The ultimate remedy obviously lies in improved and more realistic teaching of the subject in our medical schools, but meanwhile more immediate results must be obtained.

### The Practitioner's Part

To obtain these immediate results is not difficult, every suspicious case should have chest radiology arranged when first seen. Leaving arrangements till a later date and "watching" the patient in the meantime is not adequate, for he may not return. To give practical help there is reproduced below the table (with slight additions) compiled by Toussaint (1946). The occurrence of any one of these symptoms or illnesses should lead to arrangements being made for immediate x-ray examination of the chest.

Cough	Including senile patients	Influenza out of season	Particularly females aged 15-30
Haemoptysis		Recurring febrile chills	
Dyspnoea		P.U.O.	
Laryngitis		Pleurisy pleurodynia or pain in chest	
Lassitude		Loss of weight	
Bronchial catarrh		Anorexia	
Pneumonia		Anaemia and debility	
Ischio rectal abscess		Amenorrhoea	
Erythema nodosum		(unexplained)	
Phlyctenular conjunctivitis			

(The occurrence of meningococcal, military or other type of active primary tuberculosis in an infant is an added essential reason for radiological examination of adult contacts)

It may be objected that without adequate bed accommodation for the tuberculous more frequent and early diagnosis will not improve our position. It is, however, only the early case that may be treated successfully at home—an alternative to the sanatorium which is bound to gain favour as the gratifyingly successful results now being obtained by pioneers in this field are appreciated. Toussaint, working in Bermondsey and Willesden and Heller in Hounslow (personal communications), have found that domiciliary collapse therapy initially undertaken as a necessity has not only proved highly successful and enabled some patients to return to work before their sanatorium vacancy would have become available, but the waiting list can in practice be almost ignored. A second criticism sometimes advanced is the suggestion that existing x-ray facilities would be inadequate to deal with the number of films needed. My only comment upon this is again to draw attention to the fact that even the existing facilities are not being fully utilized and to point out that the mass miniature-radiograph units could be more profitably employed. Hopelessly inadequate for their present job such machines are capable of going a long way to meet an increasing demand for chest radiography by practitioners.

Finally it must be realized that the general practitioner service is the only really nationwide network immediately available to advise the sufferer and if he slips through this net a considerable delay in diagnosis is inevitable. Time lost in a case of tuberculosis can never be regained and the patient has the never repeated chance to act on the advice of the general practitioner. The patient often looks fit, he may be well clothed and have no physical signs, but he has a history to go by and he should not have sought advice. It is upon suggestive symptoms and signs that a preliminary radiograph must be ordered.

For the practitioner to be prepared when called upon to deal with chest delays—OVID

### Summary

It is shown that serious delay is usual in the diagnosis of pulmonary tuberculosis—on the average a total of 5.7 months, of which over two thirds occurs in the doctor's surgery (4 months). It is also shown that the common assumption that early tuberculosis is symptomless in the majority of cases is a fallacy. 99% of the active cases had symptoms for an average of 1.7 months before attending for consultation or radiography.

The great significance of this serious delay in diagnosis is stressed by reference to the present social importance of the disease, its rapidity of progression in the young adult, and the close correlation between prognosis and early diagnosis.

It is indicated that the general practitioner can materially improve this position by (a) realizing that incipient pulmonary tuberculosis has symptoms that may closely mimic other common and less significant illnesses, and that it may be impossible by physical examination alone to make a differential diagnosis, (b) above all, taking action in the shape of immediate reference for chest radiography in any case reporting the slightest symptoms. A table of symptoms is given as a guide to the type of case that should be so referred. Even existing radiological facilities are far from fully utilized.

Finally it is pointed out that if early cases are obtained they can be treated at once, in spite of the present bed position, if domiciliary collapse therapy is extended to more chest clinics. Practitioners therefore need not hesitate to proceed on the lines indicated. With their help the attack on tuberculosis could be highly successful without it no other method can at present reap more than a small part of the possible harvest.

My grateful thanks are due to Dr C. H. C. Toussaint, my former teacher and chief, for allowing me to investigate his cases whilst working at Willesden Chest Clinic. His inspired example and enthusiasm for early diagnosis led me to undertake this investigation.

### THE MEDICAL PROTECTION SOCIETY

Sir Ernest Rock Carling, presiding at the annual meeting of the Medical Protection Society on Sept. 29, said that it was not yet known what effect the transfer of the whole profession to the Ministry of Health would have upon litigation. The Society had had considerable experience in dealing with Government Departments, particularly the Services and the Treasury, and nothing in its past experience led it to expect that the profession would be less likely to be attacked by disgruntled patients in the future than in the past. One feature of the National Health Service might be of advantage. Medical men and dentists were obliged under the Act to keep records. Nothing had prejudiced a practitioner's case more in the courts than lack of record-keeping. Often the Society had been obliged to say that there was no defence owing to the absence of proper records. A great deal of trouble had been experienced over broken needles, and the Society had obtained reports from metallurgists which in all the cases submitted showed that there were manufacturing defects which it was impossible for the user to detect. One question which arose not infrequently was whether a practitioner should tell his patient or the patient's relatives of some mishap. It was conceivable that there were circumstances in which it was not good on medical grounds to tell the patient but in the vast majority of cases it was important that the patient should be at once informed.

Dr G. M. Stoker was introduced as the new chairman of council in succession to the late Dr Stebbing and Dr Alistair Reginald French as the new secretary in succession to Dr R. W. Durand. Sir Ernest Rock Carling and Mr W. M. Mollison were re-elected president and treasurer respectively, and all the vice-presidents and retiring members of council were re-elected. An extraordinary general meeting was then held for the purpose of passing certain special resolutions, one of which authorized the Society to cover visitors from abroad who came to work in British hospitals whether professors on exchange duty or practitioners coming over for postgraduate study.

## MEDICAL DEFENCE UNION

The annual general meeting of the Medical Defence Union was held at its offices 49, Bedford Square, W.C.1, on Sept 28, with the president Mr St J D Buxton, in the chair. Mr Buxton said that the Union had been trying to help its members in matters resulting from the National Health Service Act, particularly with regard to partnership agreements, compensation, and superannuation. A memorandum had been prepared on points arising under Sections 35 and 36 of the Act (prohibition of sale of practices and compensation). Another piece of work concerned the question of consent to operation, on which several members had requested information. The council had sought opinion from a leading counsel and had embodied his views in a memorandum available to members on request.

Provision had been made during the year, Mr Buxton continued, to overcome a difficulty which had caused the council much concern in the past. The council was now vested with full discretion in dealing with problems reported by members which affected the profession as a whole as well as the individual applicant. During the year the Union had dealt altogether with nearly 1,600 cases, 200 more than the previous year. The number of cases passed to the solicitors for attention was 117.

On the financial side the chairman said that already this year they had committed themselves to a sum in excess of £40,000 for indemnity and law expenses, and there remained more cases to be settled or fought in the courts. The highest figure until the year under review was in 1939, when these expenses were over £21,000. The subscription rate of £1 had not been changed, but at the meeting next year they might learn that the council considered it advisable to raise the subscription rate.

He concluded by expressing the indebtedness of the membership to Dr Robert Forbes and Dr P H Addison, the secretary and assistant secretary, and Mr Oswald Hempson, the solicitor. The treasurer (Dr Henry Robinson) drew attention to the fact that this year there was an excess of expenditure over income amounting to £1,340. The days when members could be charged a subscription of £1 and the Union show a handsome surplus at the end of the year were over, probably for ever.

Dr J C Matthews, Dr Henry Robinson, and Mr A Hedley Whyte the retiring members were re-elected to the council. The annual report, which was adopted at the meeting dealt more extensively with the several matters touched upon by the president in his address.

## WEST LONDON REMINISCENCES

Dr W S C Copeman, who took office as president of the West London Medico-Chirurgical Society on Oct 22, devoted his address from the chair to the story of the West London Hospital and of the Society itself from their beginnings the one in 1856 and the other in 1882 down to 1923, leaving the last quarter of a century to a later historian. Many famous names came into the narrative—Henry Maudsley, Alfred Cooper (father of Sir A. Duff Cooper, until lately ambassador at Paris), David Ferrier, Lenthal Cheatle, Charles Ballance, Stephen Paget, and among early members of the Society, John Bland Sutton, William Bennett, Jonathan Hutchinson, Howard Marsh, William Jenner, Samuel West. In 1859 Mr Ernest Hart, later editor of the *British Medical Journal* and at that time a popular contributor to *Household Words*, was elected to the staff of the West London. In the following year Sir William Crookes, the discoverer of thallium, was appointed analytical chemist to the hospital. The annual report of 1862 stated that the total number of patients seen at the hospital was 4,000 of whom 3,000 were cured.

A member of the staff, Sir William Priestley, a descendant of the famous Joseph Priestley, was appointed physician-accoucheur to the household of Queen Victoria, and attained additional fame by sending in a bill for his attendance. The bill was paid, but Dr Copeman thought his court appointment

lapsed subsequently. The first reference in the hospital reports to the nursing staff was in 1882 when seven nurses were employed, but by 1898 there were 42 nurses. Those in training received no salary during the first year £15 during the second, and £20 during the third, and any time off (including sick absence) outside the annual holiday of two weeks (three for sisters) had to be made up before they could matriculate.

The Society, formed as a result of a meeting of medical men convened at the hospital, took a high ethical line from the beginning. In its first year it expelled a member who had put 'advice gratis' on his plate. The Society was caught on a wave of bacteriological enthusiasm in the late 'eighties when, following an address by Mr (later Sir Charles) Ballance, it was put on record that "probably within measurable distance of time each medical school will possess its own bacteriological laboratory, and this subject will be included in the curriculum". At the next meeting attention was drawn to the unsatisfactory nature of the operating theatre at the hospital, where out of 69 cases in the hands of one surgeon 11 had died of sepsis or gangrene, although 'we are all antisepticians at the West London now'.

Meetings of the Society at about this period were notable for the length of the discussions. One result of this verbosity was that the editor of the *British Medical Journal* refused to print reports of the meetings for a couple of years until a deputation induced him to relent. Since that time, remarked Dr Copeman, it had been the custom to invite the editor to the annual dinner. In 1900 a special meeting was called by the Society to discuss the possible use of motor cars by medical men, but owing to the lack of interest nobody except the officers of the Society turned up. A better attended meeting discussed at length the topical question of the best form of saddle for the safety bicycle.

In concluding his survey Dr Copeman referred to the fact that in recent years a vigorous medical centre had grown up in the Society's area in the shape of the Postgraduate Medical School of London in association with Hammersmith Hospital. On this same evening the Dean of the School, Dr C E Newman, and a number of distinguished representatives of the staff were admitted to membership of the Society.

## Preparations and Appliances

### NON-TOOTHED DISSECTING FORCEPS

Mr RODNEY MAINGOT, surgeon to the Royal Free Hospital writes. This non-toothed dissecting forceps is a modification of McIndoe's forceps and is adapted from the pattern commonly in use in the United States. It is useful for holding

Non toothed dissecting forceps with spatula ends

intestines during anastomosis and also in suturing the various layers of the abdominal wall. As the cross serrated spatula like ends do not injure the tissues when used during dissection or suturing, it has many advantages over the ordinary forceps employed to-day. These forceps have been carefully made to my instructions by John Bell and Croyden, London.

The Chelsea Clinical Society held its opening dinner meeting on Oct 12 at the South Kensington Hotel, with the president Mr Nils Eckhoff, in the chair. Dr Geoffrey Evans read a paper on 'Empiricism in Medicine' before 75 members and guests. Dr Sundell, Mr Geoffrey Parker, Dr Daynes and Dr Lankester took part in the discussion which followed.

## Correspondence

### H 11 in Malignant Disease

SIR—On behalf of the Hosa Research Laboratories we ask you to publish the following reply to the report (Oct 16 p 701) of the committee appointed by the Medical Research Council. The terms of reference of the committee were "to examine the evidence upon which is based the claim that H 11 is of value in the treatment of cancer in human beings." That evidence has not been examined.

1 *The report of the committee is based on only 27% of the 4700 (now 5600) cases*—These 139 cases out of nearly 5000 are not random samples as stated in the report since they were chosen from a selected group of 1000 cases which had died or ceased treatment and which in turn were selected in alphabetical order. The Laboratories are advised by a qualified statistician that the findings are therefore statistically fallacious and give no true impression of the total cases upon which the claim is based.

2 *The cases quoted from this selected group are atypical*—Brief case records of twelve typical cases showing H 11 inhibitory action are appended. These (and all other cases) have been treated and reported upon by doctors and hospitals independently of these Laboratories. All of these and many others were available to the committee but have been ignored.

3 *Advanced nature of the cases treated*—The report avoids mention of the fact that all the cases treated with H 11 were advanced inoperable considered untreatable, and rejected as hopeless by the clinicians concerned.

4 *Results too frequent to be fortuitous*—In such advanced cases the high frequency and great reduction in tumour size caused by H 11 reported in large numbers of cases ignored by the committee cannot possibly be attributed to reduction of inflammation. Whether or not necrosis as a mode of regression is responsible for disappearance of tumours treated with H 11 (for examples see appended cases) is of no material consequence to the matter under discussion.

5 *Relief of pain*—The high proportion of cases—e.g. 65% is based on figures quoted by the committee—in which pain is relieved does provide evidence of the value of the treatment. This is indicated by the facts that (a) loss of pain frequently occurs in cases in which narcotics had previously been necessary, (b) relief of pain commonly effected by H 11 in advanced cancer cases is not produced in patients suffering pain due to other causes, (c) histological evidence at the Laboratories ignored by the committee indicates that the relief of pain is due to inhibition of peripheral tumour growth.

6 *The experimental work is outside the terms of reference of the committee*—On Feb 19 1945, the secretary of the committee wrote: "It is not within the terms of reference of the committee to examine the experimental evidence. Being accordingly concerned solely with clinical data."

7 *The experimental work which has been done on the Twort carcinoma is useless*—Table II shows that far more spontaneous regressions occurred in the controls than in the experimental animals. Which is supposed to be correct? Properly selected, the control tumours at these Laboratories show a spontaneous regression in 4% of less than 4%. The tumour forms a reliable one in 80 to 90%. The number of 'takes' varies from 80 to 90%. The Twort Laboratory reported a 90% take with the Twort carcinoma. The Twort Laboratory reported a 90% take with the Twort carcinoma. The Twort Laboratory reported a 90% take with the Twort carcinoma.

8 *The Twort Laboratory reported a 90% take with the Twort carcinoma*—Since the investigators performed the work on the Twort carcinoma, they should have reported the correct dosage work on the other side. The Twort Laboratory reported a 90% take with the Twort carcinoma. The Twort Laboratory reported a 90% take with the Twort carcinoma.

9 *The Twort Laboratory reported a 90% take with the Twort carcinoma*—The Twort Laboratory reported a 90% take with the Twort carcinoma. The Twort Laboratory reported a 90% take with the Twort carcinoma.

much as  $10 \times 13$  mm. Such wide variation does not allow a reliable bio assay to be performed. In spite of the fact that some tumours were many times the volume of this, all nevertheless were given the same dosage—and that a random dosage.

(d) *Misleading and erroneous statements in the report*—Mention must be made of one in particular, that "Mr Thompson, however, rejected five control and two experimental animals for reasons unstated." On March 25, 1947, Mr Thompson wrote to the secretary of the committee fully explaining that these were rejected because fictitious figures had been given by the investigators to tumours which had not been measured. On June 30, 1947, every member of the committee was sent this information by the Laboratories. This statement should be retracted.

7 *Summary*—We consider that in view of the complete inadequacy of the clinical investigations and the unreliability of the experimental work no serious investigation has been attempted. The Laboratories have received no intimation from the Medical Research Council that the process of examining the evidence had been terminated nor that publication was proposed. The Laboratories remained completely unaware of the report and its publication until the issue of the *British Medical Journal* containing it.

Abundant and incontrovertible evidence obtained from doctors and hospitals and open to qualified inspection exists at the Laboratories that H 11 can inhibit malignant growth in the human being—We are etc,

J H THOMPSON

G J W OLLRENSHAW

Sunbury-on-Thames, Middlesex

### CASE REPORTS

Case 1—F, 56 Papillary cystadenocarcinoma (sectioned) R ovary. First seen late 1944, visible and palpable tumour from 1 in below umbilicus into pelvis. Radiographs suggested pressure on alimentary tract from without. Refused operation 14/3/45, consented. Subtotal excision only possible owing to deep fixation to broad ligament. 4/45, deep x ray 3 weeks. 8/45 abdominal swelling recurring diagnosed recurrence and 'untreatable'. Prognosis under six months. 6/9/45 commenced H 11 weight under 8 st, falling, severe hypogastria and R I F pain, some ascites increasing abdominal mass is above. 23/11/45, no pain for two months, weight 8 st 2 lb abdominal mass doughy, no ascites now. 10/4/46, weight 8 st 4 lb no pain, abdomen isq, general condition good, housework. 23/3/47, examined under anaesthetic by surgeon who originally operated. No evidence whatsoever of carcinoma or obstruction or other abnormality. Ceased treatment. 9/48 condition normal in all respects. Survival from commencing H 11 over 3 years.

Case 2—F, 51 Carcinoma (sectioned) of ovary, excised 10/6/41, leaving clearly defined peritoneal metastases *in situ*. Massive ascites, recurred post-operatively, with 6 paracenteses (average 3 gallons) before starting H 11 on 1/7/41. 9/41 ascites absent since 8/41. General condition improved, gaining weight. 4/42, ceased treatment, general condition normal, no ascites (no paracentesis since H 11). NAD abdomen or pelvis. Current report normal health sign and symptom free. Survival from commencing H 11 over 7 years.

Case 3—F, 47 Carcinoma descending colon, first symptoms mid 1945. 19/10/45 laparotomy inoperable primary, metastases in omentum glands, left ovary. 31/10/45, commenced H 11 primary palpable  $2\frac{1}{2} \times 1\frac{1}{2}$  in some ascites, occasional blood and mucus per 17/9/46, steady general improvement, nil abnormal now found clinically. 4/11/46, ceased treatment. 8/48, normal in all respects. Survival from commencing H 11 3 years.

Case 4—M, 64 Osteosarcoma (sectioned) head of R tibia. Paget's disease present many years, sarcoma developed 11/44, confirmed by x ray. 12/44, 6/45, onset increasing cough. 7/9/45, chest radiograph showed multiple secondaries upper and mid zones both lungs. 8/10/45 commenced H 11 dyspnoea increasing cough, occasional haemoptysis. 12/1/46 x ray, some improvement all opacities reduced. General condition static. Radiographs on 19/6/46 8/11/46 30/7/47 *et seq* indicate lung metastases static to date. No haemoptysis since 4/46. General condition static. Survival from commencing H 11 3 years.

Case 5—M, 43 Carcinoma (sectioned) of rectum first diagnosed 2/46. 4/46 laparotomy and biopsy. Primary operable but liver metastases present, therefore colostomy only. 3/47 primary grown and now fills lumen of rectum now considered inoperable. 11/3/47, commenced H 11 intermittent local pain weight steady  $8\frac{1}{2}$  st, primary as above growing liver not palpable. 4/47, gained 3 lb weight, primary slightly softer more mobile, lumen larger, liver isq. 12/12/47 seen by surgeon. Primary now freely mobile and considered operable. 29/1/48 complete abdomino-perineal excision of primary with ease, all observed malignant tissue removed. No evidence now of the liver metastases noted at first operation. Section

ocarcinoma, but showing central necrosis attributed to H 11 4/48, wound healed sign and symptom free 9/48, ditto Survival from commencing H 11 19 months

Case 6—F, 45 Epidermoid carcinoma (sectioned) of cervix uteri Onset of symptoms 3/44 Radium early 4/44 after biopsy 3/46, readmitted for vaginal haemorrhage Telangiectasis near ureteric orifice was only abnormality found 25/6/46, examined under anaesthetic and by cystoscopy telangiectasis still present, no other abnormality 1/47, small mobile hard mass R pelvis, 'certainly a recurrence', no further treatment possible 26/6/47, commenced H 11 weight 7½ st, falling intermittent severe pain (morphine), pelvic recurrence as above, growing purulent vaginal discharge 14/10/47, weight 8 st 10 lb no pain now (no morphine), recurrence not now palpable, hospital report 'improvement spectacular 29/2/48, ceased treatment 7/48, normal health Survival from commencing H 11 16 months

Case 7—F, 67 Malignant melanoma (sectioned) skin of arm, excised 1/4/46 Local recurrence, with secondaries on leg and face, early 1947 Radium 1/4/47 without response 30/9/47, commenced H 11 weight steady 9 st, no pain, all lesions growing 24/11/47, all lesions much smaller smaller ones having disappeared 20/1/48, no lesions found 29/2/48, ceased treatment 6/48, normal all respects Survival from commencing H 11 13 months

Case 8—F 50 Carcinoma of cervix uteri Onset of symptoms 2/47 4/47, deep x ray 19/6/47, commenced H 11, radiotherapist reported parametrium too much involved for deep x ray or radium, inoperable Weight 9 st mild pelvic pain, primary spreading 16/10/47, weight steady no pain now up 24/1/48, radiotherapist reported, 'There has been quite a striking improvement in the state of the pelvis presumably due to H 11 Feels better and pain not such a problem' 13/7/48, weight over 11½ st, no symptoms radiotherapist reported, 'Vault of vagina and cervix clear of malignancy, possible suspicious induration L uterosacral ligament I see no reason for interference with the H 11 therapy 1/10/48, gynaecologist reported cervix normal less parametrial infiltration Treatment continues Survival from commencing H 11 16 months

Case 9—F, 54 Carcinoma (sectioned) cervix uteri Onset blood-stained discharge 9/44 First reported 5/47 diagnosis prolapse 7/47 admitted, carcinoma diagnosed (biopsy) inoperable 26/8/47, radium for one hour only Discharged 4/9/47, no further treatment possible 20/9/47, commenced H 11 weight 9 st 2 lb, falling, no pain general condition fair, primary easily palpable, growing 24/1/48, weight 10 st general condition better, vaginal examination primary considerably smaller 11/5/48, gained 1 lb weight, no symptoms primary half its September size, no evidence of metastases 11/6/48, seen at hospital, no trace of carcinoma 26/7/48, ceased treatment 15/9/48, is q Survival from commencing H 11 13 months

Case 10—F, 41 Carcinoma (sectioned) L ovary Admitted 2/44, pelvic swelling 12/2/44, laparotomy malignant mass L lower pelvis involving L ovary and colon, inoperable, biopsy 23/11/44, commenced H 11 moderate lumbar and rectal pain hard mass filling pelvis but not palpable abdominally, glands palpable to L of sacrum growth apparently stationary since 2/44 21/4/45 no pain now, p.v. scarring abdominally is q 9/6/45 weight steady no pain few small hard masses in LIF scarring round cervix and corpus uteri, but now some mobility, slowly commenced cessation of treatment 27/4/48, alive, well symptom free, abdominal condition static, masses now very small hard resembling fibrous (scar) nodules Survival from commencing H 11 almost 4 years

Case 11—F, 62 Carcinoma L lower bronchus 7/5/43, chest radiograph L lung field increased opacity from above downwards, corresponding with lower lobe, greater towards heart indicates mass in lung, bronchus constricted at one point diagnosis as above 27/4/44, commenced H 11 primary radiologically stationary No previous treatment 25/8/44, condition static but gained 2 lb weight 1/45, x ray film, lung mass completely liquefied ceased treatment 4/45 all fluid absorbed 1/47 sign and symptom free since last report 4/48, is q Survival from commencing H 11 4½ years

Case 12—Transitional celled carcinoma (sectioned) of bladder 2/41-5/41 diathermy and deep x ray to primary with good result 9/41, secondaries in cervical and lumbar spine deep x ray 9/41-11/41 when liver first enlarged no further treatment contemplated 1/42 commenced H 11 weight under 7 st bed ridden, jaundiced severe spinal pain liver grossly enlarged with palpable nodules 15/3/42 weight 7½ st no pain now walking steadily, some work, liver palpable but now no nodules jaundice cleared 5/5/42, weight 8 st 2 lb no pain, walking out liver smaller and much softer 1/7/42, ceased treatment 8/42, cystoscopy bladder normal Radiograph entirely good 10/42 back at full time work 1/43, radiograph bony changes in spine stationary and sound, symptom free 25/6/45 weight over 10 st sign and symptom free, radiograph showed spinal lesions now completely re-ossified Reports subsequently to date indicate normal health, sign- and symptom free Radiotherapist commented no similar result obtained by radiotherapy alone Case published *BMJ* Aug 14 1943 (p 211) Survival from commencing H 11 over 6½ years

SIR,—I have read with much interest the report (Oct 16 p 701) of the Medical Research Council's committee on this mysterious substance H 11. The conclusions of the report are clearly overwhelming, yet I would venture to make one criticism there has been no controlled clinical trial of the substance

The Hosa reports published are obviously valueless from the point of view of assessing the effects of H 11. Nevertheless they would appear equally valueless in proving any lack of effect from H 11. Although the animal experiments are conclusive in themselves they are not necessarily an exact parallel to the condition in man. To quote but one example stilboestrol is an accepted treatment for human prostatic carcinoma and yet oestrogens are powerful carcinogens to experimental animal. I would hasten to add that, personally I have no faith in H 11—I am, etc,

Twickenham Middlesex

DAVID WHEATLEY

SIR—In your leading article on the above subject (Oct 16 p 716) you say that many organic substances have been employed as growth controllers and that 'all have much the same effect'. There is a transient diminution of pain improvement in appetite and sense of well being, and in many cases a diminution of the size of the tumour, often with softening at the margin or throughout. Very rapidly, however, the malignant process resumes its downhill course.

It is the claim of the Hosa Laboratories as I see it that one such substance named for convenience H 11, has been investigated in much more detail than has ever been done before and that in a few cases the inhibitory action has been so far intensified that incurable growths have actually disappeared and the malignant process has not resumed its downhill course. This is more than Mr Thompson would ever claim, but I have before me three case reports which appear to prove that such a claim can be made good. Even if there should be only these three cases in three thousand there would still be a case for inquiry, for this proportion far exceeds that claimed by anyone for spontaneous regression in human beings, a condition much talked about—but has any medical man in this country ever seen a case of cancer, histologically proved, which recovered after all treatment had been given up as hopeless?

I admit, of course, that Mr Thompson's results lack controls and stand up badly to statistical methods elaborated for the analysis of quite different material. He has inevitably been most severely handicapped by the fact that he is not a medical man, and by the further facts that the treatment is long uncomfortable for the patient, and unsuitable for administration in hospital. How could he obtain controls or meet a demand for scientific recording beyond the scope of the general practitioner? He has moreover felt obliged to confine H 11 treatment to those adjudged to be hopeless cases, beyond the reach of surgery or any radiation. Nor has he had any opportunity for testing different dosages on human beings. In spite of all these very heavy handicaps he has produced such results as those now before me and, for all I know has others similar. These cases do not appear among those published in your last issue. They were presumably missed by the random sampling procedure favoured by the committee of the Medical Research Council. Nevertheless that committee states 'Enough information is now available on which to form an opinion and further work on the records is not advised and your editorial announces a verdict of tried and found wanting.'

I would suggest that Mr Thompson has been ill advised to rest his very moderate case (he claims no more than a significant inhibitory action) upon the slippery basis of animal experiments with the Twort cancer and unselected case records which were bound to be unsatisfactory by accepted standards. But I would suggest that your leading article and the committee's reports (p 701) are equally at fault. Here in my hand are three case reports of hopeless cancer restored to health after treatment with H 11. These cases were among the Hosa records. Did the committee miss them? If it did how can its opinion that no further record work is advisable be accepted? If it did not, if it actually considered these cases why did it suppress any mention of such striking results? *Quis custodiet ipsos custodes?*

I do not wish to close this letter on a tendentious note nor to involve anyone connected with the Hosa Laboratories in my

personal views I have had no communication with Mr Thompson for over a year, but I am expecting to see him this week. I therefore send this letter to you before I can possibly be influenced by his opinions upon the report. In conclusion, I would suggest that a purely clinical committee should now investigate the Hosa records, not in order to produce a statistical summary but to report whether or not these records contain any evidence which warrants the continued use of H 11 and, if so, what further steps ought to be taken—I am, etc,

Sevenoaks Kent

GORDON WARD

### Bronchial Asthma and Thiopentone

SIR,—I beg the opportunity of reporting the following case in the hope that it may serve as a warning against the administration of thiopentone to patients suffering from bronchial asthma

A woman, aged 49, was admitted to hospital with carcinoma of the breast she gave a history of 'bronchitis and asthma' for the last sixteen years. General examination showed no abnormality of the cardiovascular system, and examination of the chest revealed increase in the respiratory phase on auscultation and rather high pitched rhonchi over both lungs.

On the morning of operation she was given atropin sulph gr 1/100 (0.65 mg) at 9.40, and anaesthesia was induced with thiopentone (10 ml of 5% solution) at 10.15 to be followed by nitrous oxide, oxygen, and "trilene". The patient became cyanosed as soon as the thiopentone had been given, and in spite of vigorous movement of the diaphragm and of the thoracic cage it was obvious that no air was entering the lungs. Laryngoscopy revealed a perfectly patent larynx, and the diagnosis of acute bronchial spasm was made.

By this time a little respiration had begun to take place, but the patient was still deeply cyanosed. A little ether was added to the oxygen, which had been flowing throughout, and an injection of 5 minims (0.3 ml) of 1 in 1,000 adrenaline hydrochloride was given intramuscularly. At once the spasm became less marked, but it was at least half an hour before normal respiration took place.

I feel that the danger of administering thiopentone to asthmatics is not widely enough recognized and hope that this letter may serve as a reminder of the dangers inherent in this procedure—I am, etc,

Leicester

BRIAN D L JOHNSON

### Heart Block in Young People

SIR,—In the *Journal* of Dec 6, 1947 (p 906), we published a paper on heart block in young people. We have since had a communication from a member of the medical faculty of the University of Naples. We regard his letter as one of considerable interest for it demonstrates in a striking manner how little the functional capacity of the heart may be affected by complete heart block in the young individual. Our correspondent, Dr E B writes as follows:

I am now aged 33, married, with three lovely healthy children. My physical condition is excellent. My parents told me that I always showed bradycardia even in the first year of my life (now my normal pulse frequency is about 40 per minute). I think therefore that my disease is congenital, albeit there is another possibility since at the age of 4 I received an injection of diphtheritic toxin antitoxin mixture from a physician who suspected an initial stage of diphtheria. The first correct electrocardiographic diagnosis was established by a well known German cardiologist, Fahrenkamp, when I was 12 years old. At that time I was sent by my father for my vacation to Germany, a guest of family friends. My exceptional bradycardia had been incidentally noted by the chief of that family on the occasion of a walking tour, and it was he who took me to his friend Fahrenkamp.

Contrary to the advice of Fahrenkamp I have submitted my body to a great deal of physical stress. I have been a good tennis player, long-distance swimmer, alpinist (Mont Blanc, Monte Rosa, Matterhorn, Bernina, Piz Palu are amongst the mountains I climbed). During the last war I was a parachutist in the Allied Army and I directed a long mission in enemy held territory. The physical and psychic stress was considerable but I did not show any sign of cardiac trouble.

Some years ago I had the opportunity of measuring the output of my heart under muscular work. I give some of the experimentally determined figures (unpublished) for the maximum stress (duration of the experiment 10 minutes): pulse frequency 98, breathing frequency 24.8, depth of breathing 2,412 ml, pulmonary ventilation at standard conditions 48.9 litres per minute, oxygen consumption 2,967 ml per minute, carbon dioxide elimination 2,976 ml per minute,

respiratory quotient 1.0, alveolar carbon dioxide pressure 46.38 mm Hg, carbon dioxide virtual venous pressure 69.88 mm Hg (technique according to Bock *et al*—*J Physiol* 1928, 66, 121), blood minute volume 24.1 litres, systolic output 246 ml (an extraordinarily high figure). The oxygen capacity of my blood is 20.3 (van Slyke's technique) and the red cell count is 5.2 million per c mm.

I can endure a long period of hard work much better than brief and violent exercise, but I never suffered faintness or any sign of heart insufficiency. Some hours after great effort I have sometimes noted fatigue and sleepiness together with a very pronounced bradycardia (about 35 per minute).

"I am 5 ft 11 in (1.8 m) and weigh 12 stones (76.3 kg). My parents and four brothers are in good health."

Our correspondent sends us a copy of an electrocardiogram taken by Professor P M Franco, Naples, which is reproduced here.

Electrocardiogram taken by Professor P M Franco of Naples. The time interval is 0.05 second.

This is yet another example of complete heart block, probably congenital, which over a period of more than 30 years has proved no hindrance in an unusually strenuous life—I am, etc,

CONRAD BREMER

Leeds

### Fibrositis

SIR,—Dr James Cyriax (July 31, p 251) has described simple facts which indicate that certain symptoms and signs cannot be explained by a lesion of muscle or muscle sheath but only by a lesion of a spinal joint. His critics attempt no alternative explanation of various aches and pains but boldly state that they are due to fibrositis—a disease which was postulated much less boldly by Gowers (*British Medical Journal* 1904, 1, 117), who himself stated, "We are without any direct evidence of the real nature of these affections, such as can only be furnished by the microscope." Would not the man who made this statement if he were alive, now be the first to deny the existence of the condition he postulated?

If Dr Cyriax's critics would produce microscopic sections of fibrositis their letters would be worth publishing. Without such sections they are not worthy of space in your journal. One critic complains that fibrositis has been interred with indecent haste. Surely after 44 years it is time that we buried a disease the existence of which was entirely supposititious and which has not been proved microscopically. Let us have no more of fibrositis. Let us have more scientific attempts to explain the many things that we do not know—I am, etc.

Mt Hawthorn Western Australia

JAMES H YOUNG

### Sensitization to Sulphonamides

SIR—In the very interesting leading article about sulphonamide combinations and sensitization (Sept 18, p 563) the author says "It would be interesting if it could be shown *in vitro* that combination with protein is affected by sulphonamide concentration in the manner which these clinical findings would lead one to expect."

As far as I can see, it is just what I have shown in my paper "On Fixation of Sulfathiazole, Sulfapyridine, Sulfanilamide and Para-aminobenzoic Acid by Plasma" (*Acta Pharmacol Kbh* 1945 1, 141)—I am, etc,

Copenhagen

A HARRESTRUP ANDERSEN

\* In the paper he refers to Dr Andersen summarizes the results of his observations as follows "By the addition of

plasma to solutions of the substances to be tested and ensuing ultrafiltration it is found that the curve for the fixation by the plasma is reminiscent of an adsorption curve, and the fixation is greatest for sulfathiazole less for sulfapyridine, and least for sulfanilamide and para-aminobenzoic acid, in agreement with the ability of these substances to pass through the blood liquor barrier"—Ed *BMJ*

### Reactions to Intravenous Sclerotics

SIR—I read Dr C E Taylor's frank report (Oct 23, p 760) on his experiences with sodium morrhuate with interest. These facts speak for themselves regarding its dangerous constitutional effects. I have repeatedly emphasized these characteristics and believe that the use of this substance with its variable chemical composition should be abandoned.

Dr Taylor now proceeds to praise sodium morrhuate. "I think I have used most of the intravenous sclerotics, but I have never found that any of them approach sodium morrhuate in reliability for giving satisfactory occlusion." I must point out that whilst it has bland local effects it has potential anaphylactic and lethal power in contrast to the rest of the sclerosant family, which though they may cause injection ulcers, are seldom generally harmful.

Further may I describe one of the newer sclerosants called P2G solution? It consists of phenol crystals 2% glycerin 30% and glucose 30% in apyrogen water. Mr J W Riddoch, of Birmingham, introduced me to phenol 2% and glycerin 30%, but I did not find this so effective as the former, which has been used daily for over two years at consulting-room and outpatient injections (approximately 3000 with doses of 3-5 ml) and at operations (about 500 in volumes up to 45 ml). It has been harmless in this series of patients. It is an effective local sclerosant giving a good non painful thrombosis that is only tender to the touch for a short time. It never incapacitates a patient from pain as does "ethimolin" occasionally. When it is placed outside the vein an immediate sharp pain follows which makes the patient warn the operator to stop. This discomfort passes off within a minute by reason of the anaesthetic action of the phenol. No injection ulcer has followed its use although I have deliberately placed 2 ml around a communicating vein in the hope of causing fibrosis around it as well as thrombosis inside.

At operation the usual dose is 5-10 ml distributed down the internal saphenous vein to the knee and 5-7 ml upwards from the ankle. A maximum of 45 ml has been used several times. In a few instances the urine has been examined and a slight degree of carbouluria found but no harmful effect has been observed or reported. Occasionally after an injection a patient will report if asked a temporary giddiness but it has always passed off within a few minutes and no one has ever required a stimulant or treatment for it.

P2G is made by most of the leading drug houses. I would beg Dr Taylor to give it a trial and to finally lay aside that tonic and therefore dangerous fluid sodium morrhuate—I am etc.

London W 1

HAROLD DODD

### Femoral Hernia

SIR—I must join issue with you over the slightly disparaging way in which you dismiss A K Henry's operation for femoral hernia. In your annotation (Oct 23, p 750) you state that Henry's operation is useful for uncomplicated bilateral hernia in suitable patients but in cases of strangulation the exposure may be inadequate. Since first reading Professor Henry's article I have used his approach routinely for all cases of femoral hernia whether strangulated or not.

It has the following considerable advantages over both the low approach and the Lotheissen approach.

1 The inguinal canal is not interfered with and there is never any necessity to divide the inguinal ligament (Hev Groves).

2 Using a midline, pyramedian or Pfannenstiel incision the access to the femoral canal is much the same and with adequate muscular relaxation is good. If anything I prefer the Pfannenstiel—making the transverse incision rather more to the side of the hernia. The access is better by way of comparison, than the access to the prostate by the retropubic method.

The operation takes much less time than either of the other two methods. Using the midline approach the scalpel has only to be lifted twice before coming down on the neck of the sac—once

for the skin incision and again for the linea alba. Retraction of the peritoneum then brings the neck of the sac into view.

4 It is a simple matter to open the peritoneum in cases of strangulated hernia, and, having adequately isolated and cleaned the neck of the sac, I do this routinely in such cases, and thus one has complete control over the bowel when it is delivered from the sac.

5 The neck of the sac, which is the usual constricting agent, is dilated gently by the finger from the peritoneal aspect to allow delivery of the contents or may be divided by scissors with a finger protecting the bowel.

6 The pectineal fascia is used for closure of the canal after removal of the sac. This structure which is an astonishingly stout one, is cut with a fine bladed scalpel in such a way as to make a flap hinged either inferiorly or superiorly. The free edge is then sutured to the inguinal ligament.

It is a pity that this excellent approach, devised first by Lenthal Cheate and later independently by A K Henry appears to be so little practised—I am, etc.,

Barry Glam

H M GRANT

### Breast-feeding

SIR—I was interested to read the article by Dr Enid L. Hughes on "Breast-feeding in a Mining Town" (Sept 25, p 597), and was surprised at the low incidence of breast feeding in Newbiggin—viz, 29% at three months. Prior to reading this paper the health visitors at one of the infant welfare clinics in Southend had been keeping a record at my request of the mothers who were successfully breast feeding at three months with a view to ascertaining if any appreciable difference existed between women who were delivered in hospital and at home.

The numbers collected so far are small, 131 consecutive cases, of whom 89 were hospital deliveries and 42 home deliveries. Of the mothers delivered in hospital, including a large proportion of primiparae, 58% were fully breast feeding at three months, and of the home deliveries 55% at three months. This difference may not be statistically significant, but it certainly does not bear out the view so commonly advanced that women delivered in their own homes are more likely to have a successful lactation than those confined in hospital. It is certainly encouraging to the staff of the Rochford General Hospital, where recently much greater latitude is allowed to the mothers in having their babies in cots by the bed and in being allowed to feed them at night and occasionally "off the clock."

In addition to these infant welfare clinic cases I recently went through the records of 305 women attending the postnatal clinic in Southend six weeks after delivery. At the first attendance at this clinic all patients are asked whether or not they are breast feeding and the breasts are examined. If the child is wholly or partially bottle fed the reason for weaning is noted. Of the 305 mothers 181 were wholly breast feeding (59%), 100 mothers bottle feeding (33%) and the remaining 8% were partially breast feeding. Included in the 100 failures were seven cases where lactation was absolutely excluded—i.e., 4 stillbirths, 1 neonatal death, 1 pulmonary tuberculosis and 1 congestive heart failure. There were six cases of primary failure in lactation, the babies being discharged from hospital wholly or partially on the bottle. In a further six cases lactation was abandoned because of local difficulties—cracked, flat, or retracted nipples, mastitis, and mammary abscess. In two thirds of the remaining cases the reason for weaning was insufficiency of the milk supply—the milk "went," or the child was unsatisfied and failed to gain weight.

There remained still a substantial fraction of cases where breast feeding was abandoned because of an excessive milk supply or because the child was ill. The history given was usually, "There was plenty of milk, but it didn't suit," "The milk turned to water," "The child vomited after feeds" (or had colic, diarrhoea, or sore buttocks). Hence the baby was often weaned, although gaining weight and thriving, and very often on medical advice. Two striking examples of such advice were a baby who developed pyloric stenosis, promptly weaned without investigation, and a premature baby, 5 lb at birth, successfully breast fed for 12 weeks when 8 lb in weight who was weaned on the family doctor's advice because it had vomited on one or two occasions.

My reason for writing at such length is mainly to suggest that general practitioners should consider carefully each case of difficult lactation brought to them, bearing in mind three questions. Is the baby underfed? Is the baby overfed? Is the baby sick? If the answer to the first question is in the affirmative then the appropriate treatment is to stimulate the breasts by changing from four- to three hourly feeding advising a night feed where necessary and a complementary, never a supplementary, feed in the early weeks of lactation. This rests and allays the apprehension of the harassed mother. If the child is ill or overfed it is bad logic and bad medicine to advise weaning. Finally, I would like to suggest that if the

family doctor has insufficient time to answer these questions himself he should refer the mother to those who have more time or experience—i.e., the local child-welfare clinic or the paediatrician of the area—before depriving the baby of its surest hold on health—I am, etc.,

Westcliff-on-Sea Essex

FLORA BRIDGE

### A Jelly-fish Sting

SIR,—While diving recently I was stung on the lower lip by a jelly fish. The pain was rather like that caused by a severe sting from a nettle (*Urtica urens*), and within ten minutes there was a diffuse erythema measuring about 6 by 4 cm running from the edge of the lip towards the point of the chin with a white centre portion. An application of adrenaline 1:1,000 for some time failed to prevent an urticarial reaction, and the lip swelled, more marked in the mouth. The pain gradually became severe, the side of the face felt numb and unreal, like a Bell's palsy, and there was a considerable feeling of general irritability and malaise.

During the five days that followed the pain slowly decreased, but at the site of the sting a vesicular dermatitis developed like an impetiginous infection, with a free serous discharge. The application of both chloroform and absolute alcohol appeared to have no effect, and the scar remained for a full fortnight. A fellow bather was stung at the same time and developed many large urticarial weals on the shoulders and buttocks.

Four days after the original sting and while the area was still discharging and painful I was stung again in three places, around the left eye, between the brow and the lid, on the upper lid, and on the bridge of the nose in the area of the inner canthus. The pain commenced in the same manner, and within an hour a similar picture had developed—a large swollen area of erythema with a white centre. Tincture of *Urtica urens* was applied on damp cotton wool and the pain rapidly decreased. Next day there was a slight sensation of soreness, but on the third day there was neither discomfort nor mark. The effects of this sting had completely disappeared while the first one was still in the course of recovery.

The local swimming baths, which are tidal frequently contain jelly fish. At the end of this season the only ones which could be found were less than 2 cm long (when afloat) and about 8 mm in diameter, with a pale mauve central colouring. It is interesting, and most uncomfortable, to observe that such innocent-looking objects can cause a considerable local reaction and general malaise on what must be a very fleeting contact—I am, etc.,

Guernsey

FRANK R. NEUBERT

### POINTS FROM LETTERS

#### Gastric Herpes Zoster

Dr E. D. T. DONALDSON (Hale, Cheshire) writes: It may be of interest to your readers in view of the cases reported by Dr R. V. Stone (May 8, p. 882) and by Dr P. E. Fitzpatrick (June 19, p. 1206) to describe a further case of what I consider to be a true gastric herpes zoster. The patient, aged 65, had suffered from rheumatism of the right knee for some twelve months previously for which she was in the habit of taking upwards of 15–20 gr (1–1.3 g) of aspirin daily. In August she complained of a severe pain in the right chest radiating round to the back. This was followed a few days later by a crop of lesions typical of herpes zoster affecting the 9th, 10th, and 11th thoracic segments. The pain was intense, and she complained a great deal of anorexia and nausea. One week later she vomited about a cupful of blood stained material. This was not repeated although the anorexia and nausea continued. Her alimentary tract was rayed three weeks later—no abnormality being found. All symptoms have now cleared up apart from the original rheumatism. In this case the haematemeses may have been due to "erosion" as a result of taking aspirin, although I think its coincidence with the herpes zoster is too striking to be ignored.

#### Whooping-cough and Measles

Dr FREDERICK ROTHENBURGH (Widnes, Lancs) writes: Referring to Dr B. L. Hodges (Aug. 7, p. 312) and Dr S. N. Dhananjay (Oct. 16, p. 725) letters, may I draw your attention to the fact that a sudden attack of pertussiform cough, with heavy fits similar to real whooping-cough, can be the first sign and the pre stage of measles? This type of cough usually disappears when the measles rash appears.

## Obituary

T. SHENNAN, M.D., F.R.C.S.E.d., LL.D.

Theodore Shennan, who died on Oct. 21, was professor of pathology at Aberdeen University from 1914 to 1936. Born at Bathgate, West Lothian, on March 9, 1869, he was the son of the Rev. Alex. Shennan. He was educated at the Royal High School and the University of Edinburgh, graduating M.B. Ch.B. in 1890 and proceeding M.D. in 1895. He obtained the F.R.C.S.E.d. in 1898. Shennan had early discovered his true vocation, and as a pathologist to Leith Hospital in 1896 he began the career which was to lead him by way of the Royal Edinburgh Hospital for Sick Children and the Edinburgh Royal Infirmary to the lectureship on morbid anatomy at the university. Then in 1914 he was appointed professor of pathology at Aberdeen, and there he served his science and his university with distinction until 1936.

The chair of pathology in Aberdeen had been founded by Sir Erasmus Wilson in 1882. The first occupant of the Aberdeen chair was the redoubtable D. J. Hamilton, who, by the vigour of his personality and the forcefulness of his didactic teaching, had cast a spell which lingers to this day. Hamilton was succeeded in 1908 by one of his own students, George Dean, already a well-known serologist, but his bright promise ended with his early death after some years of ill-health. Shennan's task was an arduous one at the beginning. The outbreak of the first world war retarded the immediate development of his department, and in the post-war years, with only one assistant, he had to teach upwards of 200 students. But he triumphed over these difficulties and established for himself an enviable reputation alike as a teacher and as an administrator. He was dean of the Faculty of Medicine from 1915 to 1919 and again from 1925 to 1927. As chairman of the house committee of Marischal College for most of his tenure of the chair, he was busy with multifarious duties affecting the whole fabric of university life. He proved himself an invaluable member of the Senatus, which marked its appreciation of his work by appointing him as one of its assessors on the University Court. His lively interest in the student body never flagged; he served for many years on the committee of management of the Union and did much to encourage social and athletic pursuits.

Shennan will be remembered for his work as a morbid anatomist. The first edition of his textbook on *Post Mortem and Morbid Anatomy* appeared in 1912, the second in 1927, and the third in 1935. They embody the personal experience of a keen and accurate observer and contain a great store of useful information for the more mature pathologist as well as for the students for whom they were designed. In his earlier days he made notable contributions to the pathology of tuberculosis, particularly in childhood. There followed numerous publications in the *Journal of Pathology and Bacteriology* and elsewhere, culminating in an important monograph on dissecting aneurysms which was published by the Medical Research Council in 1934. Shennan was one of the original members of the Pathological Society of Great Britain and Ireland and a well-known figure at its meetings.—J. S. Y.

C. H. MILBURN, O.B.E., M.B., M.S.

Charles Henry Milburn, a former member of Council of the B.M.A., died on Oct. 27, at Harrogate, at the age of 88. Most of his long life was spent in his native county of Yorkshire.

His father was the Rev. J. C. Milburn, and he was born at Sheffield in 1860. While a student at the Durham College of Science he won the Tulloch scholarship in 1879, and followed this at the Newcastle-upon-Tyne Medical School with prizes and medals in anatomy and physiology, public health, and surgery. He took the M.B. and M.S. degrees of Durham University in 1882, and was house surgeon for three years at the Durham County Hospital. Then came a long period of work at Hull, where he was surgeon, and later consulting surgeon, to the Victoria Hospital for Children and the Hull and Sculcoates Dispensary. In 1897 Milburn was president of the Hull Medical Society. He joined the British Medical Association in 1882, and served it both locally and centrally,

being president in 1901 of the East Riding and North Lincolnshire Branch for fourteen years a member of Council, and vice president of the Section of Navy, Army, and Ambulance at the Annual Meeting in 1913. He was a member of the committee which reshaped the constitution of the B.M.A. in 1900 and of many other standing and special committees.

Ambulance work claimed a good deal of Milburn's energy before the 1914-18 war. He was deputy commissioner for No. 6 District of the St. John Ambulance Brigade from 1898 to 1903 and afterwards held high rank in the East Yorkshire Volunteer Brigade. He was also lieutenant-colonel (honorary colonel) 2nd Northumbrian Brigade, Royal Field Artillery (T.F.), and a member of the East Riding Territorial Association. He went to France in 1915 and worked at Rouen as surgeon to No. 2 British Red Cross Hospital, where he was popular both with his medical colleagues and with the many officers who passed through his hands as patients. After a short time as surgeon to the Wharfedale Hospital, Sheffield, he served on hospital trains in France and Belgium with the rank of major, and returned to England towards the close of 1918 to take up the duties of deputy commissioner at the headquarters of the Ministry of National Service. In 1919 he was appointed commissioner of medical services, and deputy director Yorkshire Region Ministry of Pensions, and a year later joined the staff of the Ministry of Health as divisional medical officer for the North-East of England, a post he held till 1925. Milburn was awarded the Volunteer Decoration, and for his services in the last war the O.B.E. He had many interests outside medicine. He was vice-president of the Kipling Society, and compiled for its journal a collection of epitaphs by Rudyard Kipling. He was also a justice of the peace and Deputy Lieutenant for East Yorkshire.

A kind-hearted unassuming man, Milburn went through life placidly doing whatever work came to hand. He was faithful in friendship and loyal to all the many institutions he had served. Deafness rather clouded his latter days at Harrogate, but he never complained, and it was characteristic of him that he should occupy some of his enforced leisure by combing local newspapers in search of items of medical interest for the *B.M.J.*

#### SUSAN ISAACS, C.B.E., D.Sc.

Mr. Nathan Isaacs writes: My attention has been called to your very full and just obituary notice of my wife, the late Susan Isaacs (Oct. 23, p. 763). May I offer a correction on a small point of fact which is perhaps not without interest or importance? You state that "when Geoffrey Pyke in the nineteen-twenties set up the Malting House School in Cambridge Susan Isaacs welcomed his invitation to join the staff." The staff, when the school began consisted, besides my wife, of an untrained young girl who had looked after Pyke's small boy and was kept on as general help. The fact was that Pyke had the idea of starting a small model school where the most liberal and advanced educational ideas available at the time could be brought to bear on the early education of a group of young children. He advertised the idea in an arresting form, and my wife became interested in the opportunity which thus seemed to be offered. Pyke was prepared to provide the finance necessary to set the school going on an adequate and unhampered scale and to allow scope for its further development. Everything in fact pointed to the chance of carrying out an important pioneering experiment in education under the most favourable conditions and my wife was finally persuaded to undertake to translate Pyke's idea into an appropriate reality.

Accordingly it was she who set up the school, starting from virtually nothing and on the agreed condition that she was to have an entirely free hand and the sole educational responsibility. This was only possible of course, because Pyke's educational aims and outlook were in fundamental harmony with hers, and indeed he took the liveliest interest in the working and progress of the school, to which he made various suggestive and valuable contributions of his own. However, so far from my wife "joining the staff" of the school she was actually its educational founder and remained its principal, in charge of the qualified staff which was gradually collected, until she resigned at the end of 1927. As through her work the Malting House School has passed into educational history, I trust that you will deem this correction worth publishing.

Dr. EDMUND SPENCER HEMSTED died on Oct. 7 at Kintbury Berks, at the age of 78, only about a month after the death of his wife. He was the second son of Dr. Henry Hemsted, of Whitchurch, Hants. The founder of the family was a Dutch refugee who escaped from Holland at the time of the persecution by the Duke of Alva in the sixteenth century. Nine consecutive generations of the family have included members of the medical profession. One of these married in 1746 a Miss Rustat, whose family founded the Rustat Scholarships at Jesus College, Cambridge. Of Hemsted's six brothers three were medical men and two were dental surgeons. After study at St. Mary's Hospital, Hemsted qualified as M.R.C.S. L.R.C.P. in 1892, and in 1895 started practice at Kintbury, on the Kennet a few miles upstream from the much larger town of Newbury. About the turn of the century there were two or three practitioners in Newbury of undoubted academic distinction who yet lacked the gift of inspiring hope and confidence in their patients. These qualities Hemsted had in abundance and before many years had passed he was attending not only everyone in and around Kintbury, but a good many patients from Newbury. His practice increased so rapidly that he had to take partners to cope with it, at his death he was the head of a firm of four and remained in regular hard work until the onset of his last illness in July of this year. Hemsted was for many years honorary surgeon to the Newbury Cottage Hospital. In 1914 he tried to join the R.A.M.C. but was rejected on medical grounds, so he applied himself to service in war hospitals at Barton Court Benham Court, and Albion House. He was a good shot and rider, and a keen fisherman. He contributed a paper on leucocythaemia to this *Journal* as long ago as 1896. In 1906 he married Miss Ellen Mary Stawell Brown a well-known Wimbledon lawn tennis player who narrowly missed winning a title there, and actually did win a badminton championship in 1901. Of their three children one, Dr. Edmund Henry Hemsted, is a member of the profession.—H.R.

## Medico-Legal

### THE LONGEST GESTATION PERIOD /

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A member of the Armed Forces last cohabited with his wife on Aug. 28, 1944, before going overseas. She bore a child on Aug. 12, 1945, and he petitioned for adultery with the length of the period of gestation as the chief ground. Suggestions were made that other evidence existed which might tend to prove adultery, but these were rejected by the court. Judge Topham, K.C., who was sitting as a commissioner of divorce, heard medical evidence that it was not impossible for the husband to be the father of the child and dismissed his petition. This decision was supported by the Court of Appeal on the ground that none of the unusual features of the pregnancy was sufficient to impel the court to reject the medical evidence and infer that adultery had taken place.

This period of 349 days is, we believe, the longest ever held by an English court to be possible. It supersedes the record set up last year in *Wood v. Wood*<sup>1</sup> of 346 days, and is far in excess of most of the limits set in foreign legislation. Sydney Smith says that periods of gestation beyond 300 days are distinctly unusual and suspicious, but quotes Dr. G. F. Walker's mention<sup>2</sup> in this *Journal* of one child born after 315 days and the cases in which children born after periods of 323, 324, and 336 days, weighed 12.5 lb., 14, and 16.5 lb. (5.7, 6.1, and 6.5 kg.), respectively.<sup>3</sup> It will be interesting to see where the courts stop, or rather, as they follow the medical evidence, where the medical witnesses stop.

<sup>1</sup> 1947 2 All E.R. 95

<sup>2</sup> *British Medical Journal* 1939 1 1155

<sup>3</sup> *Ibid.* 1921 2 220

The National Association of Certified Nursery Nurses states that the organization is open to all nursery nurses holding a recognized nursery certificate. Nursery assistants who have completed five years' nursery work as associate members, and nursery supernumeraries, matrons, teachers, wardens, etc., are eligible for honorary membership. The annual subscription for full membership is 5s. Particulars may be obtained from the honorary secretary, Miss Holmes, St. Anne's N.T.C., Binfield Park, Bracknell, Berks.

## terms of TONIC value

The value of a tonic cannot be measured in simple numerical units. But the essential features of such a preparation can be placed under well-defined functional headings: *restoration, formation and protection*. Syrup Minadex is well equipped to fulfil these functions. Iron, calcium and other minerals comprise the stimulatory and formative elements of Minadex. The vitamins A & D of Minadex are valuable in a protective sense. Combined in an orange-flavoured syrup enjoyable even to the most fastidious patient, these factors restore lost appetite and hasten the return to full health.

GLAXO  
**Syrup MINADEx**

In 6 oz and 12 oz bottles

Each fluid ounce contains: Vitamin A 18,000 i.u. Vitamin D 3,000 i.u. Iron and ammonium citrate 13½ grains. Calcium glycerophosphate 2 grains. potassium sodium and manganese glycerophosphates. copper sulphate.

GLAXO LABORATORIES LTD., GREENFORD MIDDLESEX BYRON 3434

## Analgesia from a travelling case

The Minnitt Gas-Air Apparatus is ideally suited to the needs of visiting practitioners and midwives alike.

Now standard throughout Great Britain, it weighs only 15 lbs., in its travelling case, measures 19" x 12½" x 5" and is specially designed for self-administration by the patient. The flow of gas-air is controlled by the patient's own respiration, complete unconsciousness never occurs, as on the verge of insensibility the pressure of the patient's finger relaxes, allowing additional air to enter and dilute the mixture. Muscular action remains unimpaired. A wheeled model for hospitals and nursing homes is also available.

**THE BRITISH OXYGEN CO. LTD.**  
WEMBLEY, MIDDLESEX RUSHOLME, MANCHESTER  
INCORPORATING COXETER & SON LTD and A. CHARLES KING LTD

## Vasodilatation

There is considerable evidence of the outstanding value of Cardophylin in producing vasodilatation. The coronary vasodilatation is manifested in an increased coronary blood flow and a beneficial effect on the myocardium. The renal vasodilatation is indicated by the powerful diuresis. It also causes bronchodilatation.

## Cardophylin

## Medical Notes in Parliament

A new Session of Parliament was opened by the King on Oct 26. The Speech from the Throne announced that legislation would be introduced changing the constitution of the General Nursing Council and to provide for the better training of nurses. Another Bill will provide for safer milk. Improvement of water supplies in Scotland and amendment of the Scottish criminal law are also proposed subjects for legislation.

Bills introduced on Oct 27 included the Education (Scotland) Bill, which proposes among other things to amend the provisions of other Acts relating to defective children and the employment of children.

Replying to Sir IAN FRASER on Oct 29 during the Debate and Address, Mr HERBERT MORRISON said that in the opinion of the Government the case for a Select Committee to consider *war pensions and allowances* was *not* made out. He pointed out that since 1946 further improvements had been made.

Mr SOMERVILLE HASTINGS spoke on the training of nurses and the legislation proposed on this point. He said the coming legislation for this purpose would succeed or fail according to whether it made possible the ultimate complete separation of the authority for training nurses from the authority for providing treatment for the sick. The constant conflict between the duty of the nurse to herself and her duty to her patients resulted in many nurses leaving the profession during training or as soon as they were trained. The employer could not successfully be the teacher, and the hospital authority which asked a matron to be both asked her to carry out an impossible task. The nurses' course need not be a long one. It could be carried out successfully in two years, but the student nurse must be a student like other students. Her life should be spent like theirs in hostel home, or lodgings. Much could be done by arranging the curriculum of the nurse and the time she spent in the wards on the same lines as those of the medical student.

The debate was adjourned.

*PPS to Mr Bevan*—The Minister of Health has appointed Mr J E Beddoe to be his Principal Private Secretary.

## Universities and Colleges

### UNIVERSITY OF OXFORD

In a Congregation held on Oct 14 the following medical degrees were conferred:

MClin—\*E G Tuckwell  
MB—E J E Jones R G Chambers Zaida M Megrah Mrs Jean C Toynebe \*H A Evans \*A R Wilson \*J W Platt \*A C Cox

\* In absence

### UNIVERSITY OF GLASGOW

A series of five lectures on "The History of Medicine," by Dr Douglas Guthrie, began on Oct 26. The second lecture was given on Nov 2 and the remaining three will be delivered in the Zoology Lecture Theatre of the University on Nov 9 and 30 and Dec 7, at 4.30 p.m. They are open to members of the University, and to the public without ticket. Details will be published in the diary column of the *Journal*.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly committee of the College held on Oct 28, with the president Lord Moran, in the chair, Dr J H Sheldon, Dr J M H Campbell, Dr E R Cullinan and Sir Weldon Dalrymple-Champneys were elected Councillors.

The following were elected representatives of the College: Dr H E A Boldero on the Committee of Management of the Conjoint Board; Dr F S Langmead on the Central Midwives Board; the President Sir Leonard Parsons, Dr H E A Boldero, Dr W G Barnard and Sir Allen Daley on the Standing Joint Committee of the three Royal Colleges; Dr C M Hinds Howell, Dr T C Hunt, Dr J C Hawksley, and Dr J B Harman on the Committee of Reference; Dr C M Hinds Howell and Dr J B Harman on the Central Medical War Committee, and Dr Donald Hunter on the Poisons Board.

Sir Weldon Dalrymple-Champneys was appointed Milroy Lecturer for 1950, his subject being "Undulant Fever, a Neglected Problem". The President announced that the Jenks Memorial Scholarship had been awarded to Martin Lawson Crossfill late of Epsom College.

### Membership

The following candidates, having satisfied the Censors' Board, were elected Members:

I Anderson MB M W Arthurton MB H S Baar MD D W Barrett MB R E Beamish MD A C Blandy MB H J Bourourline Young MD R J K Brown MB J A Campbell MB C O Carter BM F B Charatan, MB J A H Collins MB E G Cook MB R I G Coupland MB R H Cutforth MB D F Davies MB D M Davies MD P D B Davies MB W Dickson MB A Dolphun MD B V Earle MB J R D Eaton MB A El-S Eissa MB H L Ellis MD C C Ewart MB A N Exton Smith MB W Fabish MD D A Ferguson, MD H V L Finlay MB P B Fox MB T T Fulton MD I Gilbert MB S V S Govinda Setty MB M J Greenberg MB C Gresson MB J R Harnes MB R V Johnston MB E C B S Keal MB J O Laws MB A G Leishman MB I C Lewis MB G H T Lloyd MB Josephine M Lord MB L C Lum MB R H G Lyne Pirkis MB A R Lyons MD R K MacCush MB A C Macdonald MB G Macdonald MD L E McGee MB J K Martin MB H Miller MB I Miller MD E H Minors MB B S Moos MD, A A Morgan MB J Nash MD S R K Padmavati MB I C L Patch MB S H Patel MB M B Pemberton MB A R Piracha MB E MacL Poulton BM F I Rackow MB D H Reilly MD P K Renshaw MB, P L Robinson MB R S Savidge MB, J Shein MB G Skinner L R C P A W Sloan MB W H Smith MD W G Spector MB M P Spence MB J W Stephens L R C P J P P Stock MD D H P Streeton MB, J L Taylor MB R W Temple MB H R Thomson MB P A Thorn MD E Waddington MB D C Watson MB S P B Way MB B W Whitaker MD J B Wild MB H B Li Williams L R C P Iolo G Williams MB, F B M Woodhouse MB D G Wrath M B G A Wright MB

### Licences

Licences to practise were conferred upon the following 146 candidates (including 33 women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and who have complied with the necessary laws:

M S M Adams Maureen B Adams D A Ager D D Alexander H D Alexander J D Arneaud N O Ascroft K A Baker K L Batten D F Bedford D P Belgrave S Benaum G R Benetti, Elizabeth Bennett J M Bernstein A J Bervitz T B Binns J A L Bonnell P H Bracewell A T Broadbridge Ena K Bruck R J Carey J K Carter W I Carter J A Cheese Ellen M Chippindale M Cohen W W H Colmer Elizabeth D Connan, W E Cooper A A Craigen, Phyllis A M Crozier D A Davey D H Davies G J Davies Gwenhyfar Davies V J E Davies Nuala M Dowdall R W Doy Shirley R Drake B H du Heume Gwenllian Edwards A A Eley Mary G Ellis H B F Farley J Fine C A Foster Lois Gardiner R Gardner G M Gould A A Graham Edwina E Green H J A Hahn D C Hall J A H Hancock D F N Harrison J M Haughton G E Haward R B Heisch A A Hobbs J H Holden C J Hood J C Humber K M S Hume Marjorie J Ion T E Jeffreys Beryl M Joles C R Jolly D H Jones Miriam Kahn M A Kalina A J Karlish M S Katana H R Ker E Kiley G S Laing P Lancer B H Lawrence Gerda Lewin E A C Lloyd V A Lloyd Mary Lloyd Evans F A H Logie R H Longton J A Ludwig B Lytton Elizabeth G S McDowall M H Masina Leela Menon J Monckton D K Morgan D McK K Muir J G Neville W T Newman Anne Nunan H M C O Driscoll Jean M Ottaway K L Owen J J Owies O Parry Jones Jacqueline I C Payne G W Pearce M C Peterside E M Poulton D G Price Margaret D E Quinet B W Richards D F Richards J L Richards W R Riley I R L Rose Marian W Ruscoe D G Rushton J M S St John E R J Sarfati H J Sayani W K Schnarr D N M Scott Warren R G Seager Thomas S A V Serviss Pauline M Seymour Cole P W Shillito D W Smith R S Sneath D H A Sohan Margaret Speight G D Starte G A Steele Mildred A R Sulton Mary C Sumpston R L H Tasker D G Taylor Margery W Taylor J Tininer D A T Tizard Jean M Tomlinson J T Trencham S E Trickey P G Tuffnell R J Vale J S Vazifdar T Wade Evans P R Wagner Norma M Whalley F R H Wrigley J R W Wynne

### Diplomas

Diplomas in Tropical Medicine and Hygiene, in Ophthalmic Medicine and Surgery, in Child Health, in Industrial Health, and in Physical Medicine were granted jointly with the Royal College of Surgeons of England to the following successful candidates:

**DIPLOMA IN TROPICAL MEDICINE AND HYGIENE**—To the 30 successful candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

**DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY**—To J S McKenty and to the 52 candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

**DIPLOMA IN CHILD HEALTH**—To M F Moses and to the 87 candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

**DIPLOMA IN INDUSTRIAL HEALTH**—To the 12 candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

**DIPLOMA IN PHYSICAL MEDICINE**—G H Dobney, D M L Doran, Joan M Gold, G Gregg J B M Milne, K W N Palmer, J D Thompson, M E Wigfield, R W Windle.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

A meeting of the Board of Faculty of Anaesthetists was held on Oct 6, with Mr A D Marston, the Dean in the chair. Some 19 newly elected Fellows of the Faculty were introduced by the Dean and admitted to the Fellowship of the Faculty by the President of the College Lord Webb Johnson.

It was decided that whereas up to the present only holders of the Diploma in Anaesthetics of the two Royal Colleges should be

eligible for Membership of the Faculty, in future, holders of the Diploma in Anaesthetics of other recognized bodies should be eligible for admission

It was reported that there had been an excellent response to the first course of lectures and tutorials which had been organized by the Faculty. The Board is anxious to increase the scope of its teaching and is hoping to arrange for clinical instruction to be given at various non-teaching hospitals.

A Joseph Clover Memorial Lecture has been founded by the Faculty and is to be given annually. Mr A D Marston was elected to give the first of these lectures at the College on March 16 1949, after the annual general meeting of the Faculty.

The Dean presented to the Faculty a gold badge of office to be worn by Deans of the Faculty. The Board presented to the College, to commemorate the founding of the Faculty and the Fellowship, a silver claret cup, once the property of Professor Simpson and presented to him by Lord Errol, and a silver gilt cup which is a replica of a cup designed by Paul Lamerie in the seventeenth century. The Board gave a small dinner-party in the College in the evening to which a few guests were invited.

The following were elected Fellows of the Faculty: H K Ashworth, Wesley Bourne, S F Durrans, H E Karslake, Eccles A H Galley, Noel Gillespie, Victor Goldman, John Halton, A E W Idris, R W Ironside, F Barnett Mallinson, Mrs H Scott Mason, Mrs K L Oldham, Mrs E M Taylor, Ralph M Waters, Keith Woodruff.

At a meeting of the Council held on Oct 14, with the President Lord Webb Johnson, in the chair, Professor Geoffrey Hadfield was admitted as Sir William Collins Professor of Human and Comparative Pathology, and the John Tomes Prize was presented to Professor H H Stones, of Liverpool. The following were appointed Bland Sutton Scholars: Mr R J Last (reappointed) and Mrs P H Herbert.

The Fellowship in Dental Surgery was awarded to Dr Harvey H Reid (Canada) and to Professor B Gottlieb (Austria).

Diplomas of Membership were granted to R B Heisch, C I Hood, and D H K Soltan.

Diplomas in Tropical Medicine and Hygiene in Ophthalmic Medicine and Surgery, in Child Health, and in Industrial Health were granted jointly with the Royal College of Physicians of London to the following successful candidates:

**DIPLOMA IN TROPICAL MEDICINE AND HYGIENE**—C S Agrawal, M H S El Amroussi, Norah H C Clarke, B P Courtenay Mayers, K O Courtney, R McP Cross, R S Dayal, H G Edmunds, W Fabisch, J D Greco, J T Harold, G F Houston, M H Hughes, S A Jones, R Lwio, G McHugh, B U Mistry, Mok Hing Yiu, R Panigrahi, M Rech, A S Saffar, M A El Sayed, S C Sekar, A K Sen, F K Shah, V D L Smith, M L Sur, E Tustaoowski, G H Wattleay, Wu Hsueh Tsung.

**DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY**—R C Agarwal, A N Ashworth, N L Bailey, S C Banerji, G M Barling, B A Bembridge, T A S Boyd, R S E Brewerton, J B Bunting, T Chadderton, R M Chambers, Shing Chue Chan, P M Chaudhuri, E S Dismore, N F Donaldson, S Etzine, J H W Fagan, P I Franks, S Galbraith, P J A Gormley, T B Gupta, K O Gyi, A Harrison, J R Hudson, P J L Huoter, R I Jaffe, K R Kesavachar, T G Kletz, M Lerner, H F T MacFetridge, B A Marshall, T S Maw, M Mohsin, L Myers, W J Naughton, M J Nikosiewicz, Eithne J O'Riordan, C M Phillips, S T Puttanna, J E Pyper, J L Reiss, K Rubinstein, H Saiduzzafar, A E Sawday, M Shaffi, E Shenken, N I Sreenivasan, C S Swan, J Swartz, A K Tulloch, J M Whaites, P C Yates.

**DIPLOMA IN CHILD HEALTH**—H C Allan, S Balasingam, Marion B Bethune, S Bhattacharjee, Camilla B P Bosanquet, T A Braod, E J S N Briggs, F B Bromfield, H J S Brown, Isobel Brown, M F G Buchanan, L J Russell, Helen A Cawson, A B Christie, Margaret T Collins, W D D Cooke, E G A Crawshaw, J U Crichton, P O Crossfield, G H R Curnock, W Davies, A W Dickie, M H C Dyson, P D Fergusson, R J L Ferris, H J W Fisher, I H Fletcher, J O Forfar, Frances A Fouracres, Gin Shan Yeh, Janet F Graham, J R Harries, Dorothy A Harvey, K ul W Hazrat, Betty E Howarth, M C Hudson, Bennett Pauline, M Jackson, J C Johnson, R St J R Johnston, G Kiriane, Stephanie A Laing, B M Laurance, J A Leitch, R Lindop, R H G Lyne, Pirkis Kathleen, J McCarthy, Muriel M McLean, H B Marsden, Margaret St C Masson, Gladys A Meigh, Rachel Menashe, S M Merchant, H R A Michelmore, Dorothy J Mi, N Montgomery, N M Nicholson, W B, A P Radford, Elizabeth Radovitch, J T, Riley B S Rose, D C Ryan, M Shah, G, Strickland P V, Suckling, Jean C Taylor, K B Thornton, Joyce F Tucker, C H C Upjohn, D F Van Zwanenbergh, D G Vulliamy, G F Walker, J M Watt, L E Wear, S D V Weller, R W Wilkinson, Jean C Willis, B S Wood, L A Zeki.

**DIPLOMA IN INDUSTRIAL HEALTH**—T S Adisuhramaniam, M A C Dowling, W Gunn, M N Gupta, E T Harrison, G O Hughes, T H McCormack, L E J Poulter, J B Sherman, J A Smiley, J M Stuart, A R Thompson.

The Bai Jerbai Wadia Hospital for Children was recognized in respect of the posts of surgical registrar and first and second house-surgeons for a period of six months, in connexion with paragraph 23 of the F.R.C.S. regulations.

#### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

Professor D M Dunlop will deliver the Finlayson Memorial Lecture in the Hall of the Royal Faculty of Physicians and Surgeons (242, St Vincent Street, Glasgow) on Wednesday Nov 10 at 5 p.m. His subject is: The Clinical Use of the Anthistamine Drugs. Other lectures will be given in the Hall of the Faculty on Wednesdays Nov 24 and Dec 8 1948 and Jan 12 and 26 and Feb 9 1949 at 5 p.m. Details will be published in the diary column of the *Journal Medical Practitioners* are invited to attend.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct 16

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases, a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Food-poisoning at Southgate

An outbreak of food poisoning has been reported from Minchenden County Grammar School, Southgate, London, N 14. Approximately 500 pupils and staff partook of a mid-day meal served in the school canteen on Thursday, Oct 21. About 150 of those who ate the meal—it has not yet been possible to ascertain the exact number—complained of diarrhoea and severe abdominal pains during the evening of the same day or at night. In a few instances nausea and vomiting were also present, with headache, although there was no evidence of pyrexia. The symptoms passed off rapidly, all the members of the staff and most of the children attending school on Friday, Oct 22. By the following day few after-effects were reported.

The midday meal on Thursday consisted of salt beef, salad with salad dressing, potatoes, and baked almond tart. Bacteriological examination of the beef, carried out by the Central Public Health Laboratory, showed evidence of fairly heavy bacterial growth. The method of cooking the beef which had been stored in brine (concentration 16%) was as follows:

The meat was delivered to the canteen on the morning of Wednesday, Oct 20. It was immediately placed in the refrigerator in which it remained until the afternoon of the same day. It was then removed and cooked in a gas boiler for two and a half hours. After cooking the meat was allowed to cool off in the boiler during the night of Oct 20-21 being served cold with salad on the following day. It would appear that the cooling off process provided conditions in which bacteria could multiply and elaborate toxins.

An interesting feature revealed by the investigation was that similar joints from the same batch of salt beef were supplied to two other school canteens in the area and were cooked in the manner set out above. In these cases however, the meat was not allowed to remain in the boiler to cool after cooking, but was removed, placed on covered trays, allowed to cool, and was then put in the refrigerator.

Bacteriological investigations are still continuing and it has not yet been possible to identify the responsible organism. It might be stated in conclusion that conditions in the school canteen were very satisfactory and that the standard of hygiene there left nothing to be desired.

## Discussion of Table

In England and Wales increases were recorded in the incidence of measles 475, scarlet fever 246, acute pneumonia 58, dysentery 30, and diphtheria 29, while a decrease was recorded in the notifications of whooping-cough 124.

The largest rises in the incidence of measles were in Yorkshire West Riding 151, Monmouthshire 99, Essex 91 and Yorkshire East Riding 77. In contrast to the general increase a fall occurred in the south midland counties where the notifications declined from 148 to 90.

Notifications of scarlet fever have been doubled in the past six weeks since the incidence began to rise. During the week the largest increases were Lancashire 48, Essex 29 and London 28. For nine consecutive weeks a fall has been reported in the incidence of whooping-cough, the local variations in incidence were small.

The return for diphtheria was the largest for thirteen weeks. In Lancashire the notifications of diphtheria showed a rise of 14 due to an increase in the county boroughs. An outbreak of diphtheria affecting 6 persons was notified from Durham, Houghton-le-Spring U.D.

In Shropshire Oswestry R.D. 6 further cases of typhoid fever were notified. An outbreak of dysentery affecting 50 persons was notified in Essex Hornchurch U.D. The other large return of dysentery was 9 cases in Warwickshire Warwick R.D. In Lancashire only 8 cases of dysentery were notified this was 20 less than the figure for the preceding week. The largest returns of acute poliomyelitis were Lancashire 8, Middlesex 7, Northamptonshire 7 (Kettering M.B. 6), London 5 and Devonshire 5.

In Scotland an increase occurred in the number of notifications of scarlet fever 76 and whooping-cough 19 and a decrease was recorded for dysentery 18. The decreased incidence of dysentery was mainly due to a fall of 15 in the notifications from the western area. A rise in the notifications of scarlet fever was general throughout the country except in the north-eastern area where a small decline occurred.

In Eire a decrease was recorded in the number of notifications of measles 76 and whooping-cough 26 while a rise of 2 was reported for scarlet fever. These trends applied to most areas of the country. A further 25 cases of measles were notified from the outbreak in Clare Kilrush R.D. The largest returns for scarlet fever were Dublin C.B. 146 and Galway U.D. 12.

In Northern Ireland a decrease of 38 was reported in the number of notifications of measles from Belfast C.B.

## Week Ending October 23

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1389, whooping-cough 2163, diphtheria 153, measles 5303, acute pneumonia 426, cerebrospinal fever 31, acute poliomyelitis 76, dysentery 99, paratyphoid 4, and typhoid 13.

## Medical News

## Medical and Biological Abstracting

To avoid duplication of effort among certain abstracting services an Interim Coordinating Committee on Medical and Biological Abstracting was set up in October, 1947, by Unesco and will now be jointly sponsored by the World Health Organization. Arrangements have been made to exchange abstracts between some of the agencies concerned. The experiment is still in progress. The Interim Committee, believing that its work can be usefully continued, has invited certain other non-profit making organizations in the field of medical and biological abstracting to serve on it. When these invitations have been accepted, a full meeting of the Committee, which will then cease to be interim, will be held in Paris in the summer of 1949. Any organizations interested in this work should communicate with the Department of Natural Sciences, Unesco, Unesco House, 19, Avenue Kleber, Paris XVIe.

## Clergy's Appreciation of Medical Profession

The Lower House of Convocation of Canterbury recently passed the following resolution:

That at this first Session of Convocation after the inauguration of the National Health Service this House desires to place on record its grateful appreciation of the generosity and kindness shown through many generations by members of the medical profession to the clergy and their families as well as to countless other persons of small means in times of sickness and need.

The Lower House of Convocation is a representative assembly of all the clergy of the Church of England in the southern two thirds of England.

## Wessex Rahere Club

The first annual dinner of the Wessex Rahere Club was held at the Royal Hotel, Bristol on Oct 17. Dr E. R. Cullinan attended from St. Bartholomew's Hospital, and some thirty-six members were present under the chairmanship of Dr G. D. Kersley. It was agreed that membership of the club should be open to all Bart's men resident in Somerset, Wiltshire, and Gloucestershire with the possibility of extending the area later. Mr C. E. Kindersley (Bath) was elected chairman and Mr A. Daunt Bateman (3 Circus, Bath) honorary secretary for the coming year. The 1949 dinner will be held in Bath on a Saturday in October. It is hoped that any Bart's men who are interested and have not yet been in touch with the club will notify their whereabouts to the honorary secretary so that they can be kept informed of future meetings.

## Isotopes for Research

The Ministry of Supply states that radioactive isotopes have now been produced at Harwell for some months in the low-power pile to provide for the immediate needs of research workers. The production of the small pile is nearing its maximum and has recently been making about 120 samples a month, of which two thirds have been for users outside the establishment. Among the isotopes of particular use to biological workers are Na<sup>24</sup>, K<sup>40</sup>, and Br<sup>80</sup>, whose short half-lives preclude their import from America. Workers who wish to use isotopes are invited to discuss any unusual problem with the Isotope Information Officer, Atomic Energy Research Establishment, Harwell, near Didcot, Berks. Allocation of radioactive isotopes must be approved by the Isotope Allocation Committee (chairman, Sir John Cockcroft, F.R.S.). Radioactive isotopes may also be obtained from the U.S.A. and Canada, but requests must be sponsored by an appropriate authority such as the Medical Research Council. Inquiries should be addressed to the Secretary of the M.R.C., 38 Old Queen Street, London, S.W.1. The Ministry has purchased a quantity of N<sup>15</sup> from the U.S.A. and allocated some of it to the M.R.C. The rest is available for distribution to workers whose research is sponsored by the appropriate body (for medicine, the M.R.C.). At present there is a shortage of mass spectrometers for assay and the M.R.C., which has two instruments operating at the National Institute for Medical Research, Hampstead, is therefore prepared to do assay work and to advise in the preparation of samples from biological material.

## Radioactive Elements for German Research

The Control Commission has decided that radioactive elements may be supplied for medical research in Germany. They will be provided from the atomic pile at Harwell, and their use will be demonstrated by a team from Harwell.

**Halfpence for Health**

The National Association for the Prevention of Tuberculosis is an independent organization, receiving no money from the Government, whose aim is to help the tuberculous patient and to educate the public in the prevention of tuberculosis. In the last ten years it has raised about a quarter of a million pounds by selling attractive stick on labels for Christmas letters and parcels. These labels, which have been given to the N.A.P.T. by the Canadian Tuberculosis Association, are now on sale again at 4s a hundred from the Duchess of Portland, Chairman, N.A.P.T., Tavistock House North, Tavistock Square, London, W.C.1. Every halfpenny helps to keep alive the voluntary spirit which is so necessary to this work.

**Nobel Prize for Work on D D T**

Dr Paul Moller, of Basle, is to be awarded the Nobel Prize for Medicine for his discovery of the insecticidal properties of D D T. This substance was made in 1874, but it was first used as an insecticide in 1939 to check a plague of potato beetle in Switzerland. Dr Moller was working in the laboratories of the J. R. Geigy Dyestuffs Company of Basle, which in 1942 drew the attention of the British Government to the usefulness of D D T as an insecticide.

**Vitamin C in Blackcurrants**

The Ministry of Food announces that blackcurrant syrup and purée will again be available through retail chemists for children, invalids, and others in need of additional vitamin C. Children are those aged up to 18 holding green or blue ration books (RB2 or RB4). Owing to the high price of fruit this year, the maximum retail price of the syrup will be 2s 10d for a 1½ oz bottle and of the purée 1s 6d for a 9½ oz can. Both commodities will contain not less than 20 mg of vitamin C per fluid ounce.

**Mr A G Timbrell Fisher**

Mr A G Timbrell Fisher has been elected to the Fellowship of the American College of Surgeons.

**Dr A C Norman**

The King of Iraq has conferred the decoration of Insignia of the Third Class (Civil Division) of the Order of Al Rafidain upon Alfred Clarence Norman, C.B.E. M.D., in recognition of valuable services rendered by him as Director of the X-ray Institute at the Royal College of Medicine, Baghdad.

**Medical Golf**

The following are the results of the competitions at the autumn meeting of the Medical Golfing Society held at Royal St Georges, Lindsy-Rea Cup, Dr C Carron Brown (5) 3 up, Canny Ryall Cup, Dr G Armitage (5) 72, Veterans Cup, Dr D Craig (12), 74, Milsom Rees Cup, Dr A Galletly (4).

The autumn meeting of the London Irish Medical Golfing Society was held at Aldeburgh. The results are as follows: O Malley Cup, Dr R J Sandys (15), 1 down, Lett Cup (foursome), Dr T J Kellcher and Dr T Murphy 1 down, Canny Ryall Cup, Dr G Purcell (12), 70, Cahill Trophy, Dr S C Morrow (13), Mannix Cup, Dr S C Morrow (13), Veterans Prize, Dr J J Cremin (8), 79.

The London Irish Ladies Medical Golfing Society have completed a successful year with a meeting at Beaconsfield. The following were the winners of the competitions: Scratch Prize, Mrs E McGrath (19), 97, Canny Ryall Cup, Mrs K Cowles (26), 80, Foursomes, Mrs E McGrath and Mrs K Nolan (all square). The captaincy has been held by Mrs G Walters and the secretarial duties have been carried out by Mrs R Lindsy Rea. The annual general meeting is being held to day, Nov 5 at 82, Harley Street, London W.1.

**Wills**

Dr Legh Richmond Herbert Peter Marshall, of Walkernburn, Peebles shire, left £31,090. Dr Alfred Milne Goswage of Chalfont St Giles Bucks, late consulting physician to the Westminster Hospital and of the Princess Elizabeth of York Hospital for Children, left £17,236. Mr Henry Secker Walker, of Bradford-on-Avon, Wilts, left £114,937. Dr William James Deacon Inness of Horwood, Devon, late Director of Medical Services, West African Medical Staff, left £4,329.

**COMING EVENTS****London Chest Hospital**

A course of lectures and demonstrations will be given at the London Chest Hospital (Victoria Park E) on Fridays, at 5 p.m., from Nov 5 to Dec 17, 1948 and from Jan 7 to March 25, 1949. Admission is by ticket only. The fee is £3 3s, except in the case of serving and demobilized members of H.M. and Allied Forces. Applications should be addressed to the dean of the hospital. Details of the lectures will be published in the diary column of the *Journal* week by week.

**Maudsley Lecture**

The twenty third Maudsley Lecture will be delivered by Mr Clud Mullins before the Royal Medico Psychological Association at 26, Portland Place, London, W., on Friday, Nov 12, at 2.15 p.m. His subject is "Psychiatry in the Criminal Courts." Psychiatrists and other medical practitioners, psychologists and members of the legal profession, teachers and students, and all interested persons invited to attend the lecture. Admission is without ticket.

**S.E. Metropolitan Regional Tuberculosis Society**

The inaugural meeting of the South East Metropolitan Regional Tuberculosis Society will be held at the County Hospital, Sevenoaks Road, Orpington, Kent, on Nov 13 at 10.30 for 11 a.m. The Constitution of the Society will be discussed and approved and the assembly will be addressed by the Senior Administrative Medical Officer of the Region, Brigadier H. L. Glyn Hughes. All interested practitioners in the Region, and particularly those engaged in chest work, are invited to attend.

**Public Health Congress**

The provisional programme of the Public Health and Municipal Engineering Congress and Exhibition, to be held at Olympia, London, from Nov 15 to 20, has been issued. The programme is not yet complete, but 21 sessions have been arranged under the auspices of the leading professional institutes and associations, and 26 papers will be read, the subjects, to which additions will be made including hospital administration in the National Health Service, mental health services, refuse storage, sewage, rural water supplies, water supply gathering grounds, district heating, communal health facilities on housing estates, housing of old people, plumbing research, quarrying and highway engineering, planning of a new town, park organization and equipment, and health visitors work. The Exhibition and Congress are being held under the patronage of the King and the presidency of the Minister of Health, and the Ministries of Health and Transport are both represented on the organizing council, the chairman of which is Sir Roger G. Hetherington. The joint honorary secretaries are Mr G. P. Warner Terry and Mr C. W. Scott Giles, and the Congress address is 84, Eccleston Square, London, S.W.1. Contributions of particular interest to the medical profession include papers by Sir Ernest Rock, Carling on 'The Provision of Homes for Old People' on Nov 15, at 3 p.m., by Mr George Watts on 'Hospital Administration in the National Health Service' on Nov 16 at 10.30 a.m., by Dr Rees Thomas on 'Mental Health Services' on Nov 17, at 10.30 a.m., by Mr A. R. Kerrell Vaughan on 'The Provision of Communal Health Facilities on Housing Estates' on Nov 19, at 10.30 a.m. and by Miss B. Townsend on 'The Health Visitor's Place in the Health Team' and Miss E. C. Jackson on 'Day Nurseries, their Uses and Abuses' on Nov 20, at 3 p.m.

**Films on the "Neuraxis"**

A joint meeting of the Scientific Film Association and the Royal Society of Medicine will be held at 1, Wimpole Street, London, W. on Monday, Nov 15, at 8 p.m. when Professor Pedro Belou, professor of anatomy at the Faculty of Medical Sciences, Buenos Aires, will show his films on the Neuraxis. Fellows of the Society and visitors introduced by Fellows will be welcome.

**SOCIETIES AND LECTURES****Monday**

MEDICAL SOCIETY OF LONDON, 11 Chandos Street, Cavendish Square, W.—Nov 8, 8 p.m. Pathological meetings.

UNIVERSITY COLLEGE, Gower Street, W.C.—Nov 8, 4.45 p.m. *The Electron Microscope and its Biological Applications* by Dr E. M. Crook, M.Sc., Ph.D.

WESTMINSTER HOSPITAL SCHOOL OF MEDICINE, Meyerstein Lecture Theatre, Horseferry Road, London, S.W.—Nov 8, 5.30 p.m. *Pyelonephritis and Renal Suppuration*. Clinico-pathological meeting.

**Tuesday**

CHELSEA CLINICAL SOCIETY—At South Kensington Hotel, 47, Queen's Gate Terrace, London, S.W.—Nov 9, 7 for 7.30 p.m. *The Value of Chronophotography in Foot Disabilities*. Discussion to be opened by Mr J. H. Hanby, F.R.C.S.

GLASGOW UNIVERSITY—Nov 9, 4.30 p.m., *The Evolution of Medical Education in Scotland* by Dr Douglas Guthrie.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Nov 9, 5 p.m. *Scars* by Dr H. Corsi.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-2, Gray's Inn Road, London, W.C.—Nov 9, 11.30 a.m. *The Physical Principles of Audiology and Hearing Aids (II)* by Dr T. S. Littler, 2.15 p.m. *The Respiratory Tract in Infectious Diseases* by Dr E. H. R. Harries.

INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London, W.C.—Nov 9, 11 a.m. *Latent Syphilis* by Dr W. N. Mascall, at St Peter's Hospital, Henrietta Street, London, W.C.—Nov 9, 5 p.m. *Calculus Disease of the Bladder and Urethra* by Mr F. R. Kilpatrick.

*eight minutes to go . . .*

Doctors today find that a large number of their patients complain of constant tiredness, of 'finding everything too much', of 'feeling generally run down'. Cases of debility and lassitude caused by present-day conditions are becoming increasingly prevalent. For these conditions 'Vibelan' is of particular value. It counteracts B vitamin deficiencies, containing as it does the principal members of the B group in the balanced proportions which are necessary for effective utilisation of proteins, fats and,

more especially, carbohydrates. Each tablet contains vitamin B<sub>1</sub> 0.5 mg, riboflavin 0.75 mg and nicotinamide 7.5 mg, in a yeast extract base. Four tablets provide the normal daily requirement of these vitamins. 'Vibelan' is available in bottles of 50 tablets. Further details are available on request.

Of the greatest importance is training in our tender years—but once a lesson becomes a habit it is not easily forgotten.

Often the physician will have the task of stressing the importance of regular bowel movement and the prescription of 'PETROLAGAR' will greatly assist in establishing this 'habit-time' safely and pleasantly.

Exceptionally palatable 'PETROLAGAR' emulsion mixes intimately with the bowel contents thereby stimulating natural peristalsis without the irritating effect of cathartics.

## Safe, effective bacteriostasis with 'SULFEX' in nasal and sinus infections

The intranasal use of 'Sulfex' ensures prolonged local bacteriostasis and prompt vasoconstriction. The microcrystalline ('Mickraform') sulphathiazole forms a fine, even 'frosting' over the nasal mucosa, and makes possible the maintenance of high local concentrations with the minimum of systemic absorption. The shrinking action of 'Paredrinex' renders the tissues more accessible to the sulphathiazole and promotes ventilation and drainage. 'Sulfex' is indicated in nasal and sinus infections—particularly those secondary to the common cold—and in sore throat. It is equally suitable for children and adults.

'Sulfex' is an aqueous suspension of microcrystalline ('Mickraform') sulphathiazole, 5%, in an isotonic solution of 'Paredrinex', 1% (pH 5.5 to 6.5). Issued in 1 oz. and 8 oz. bottles.

## Painless INTRAMUSCULAR INJECTIONS

e.g. of PENICILLIN, LIVER EXTRACTS,  
ARSENO-BENZOLS, BISMUTH, etc.

Many substances create some pain on intramuscular injection. Novutox injected at the same time will prevent this pain.

Most substances are compatible with Novutox, which is also non-destructive to penicillin during the time that the latter is undergoing absorption.

Mixtures with Novutox should be made  
immediately before use **ONLY**

**NOVUTOX**  
*Self-Sterilising*  
*Local Anaesthetic*

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl, 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinatoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Hodgkin's Disease

**Q**—What is the latest treatment of Hodgkin's disease? What are the results of treatment with nitrogen mustard? Is irradiation still the most efficient treatment?

**A**—It is optimistic to regard any treatment for Hodgkin's disease as efficient. Irradiation remains the standby, and it will usually cause the enlarged lymph nodes to shrink, though most patients finally become "radio-resistant". The nitrogen mustards, especially methyl-bis-(beta-chloro-ethyl) amine hydrochloride, have been used recently and in many instances will cause a temporary remission in the disease. This substance does not cure Hodgkin's disease, and in the early stages radiotherapy is to be preferred. Nitrogen mustard is often effective in relieving—albeit temporarily—the symptoms of the generalized stage such as fever, cachexia, prostration, pruritus, and the pain of skeletal infiltrations. Some patients whose disease has become resistant to irradiation are improved by a course of this drug.

Stilboestrol in Dysmenorrhoea

**Q**—Is there any danger in treating severe dysmenorrhoea with stilboestrol indefinitely? The case I have in mind is a patient of 22 who has been having 1 mg stilboestrol daily for the first ten days of the menstrual cycle. Recently she had a dilatation and curettage but this failed to relieve the dysmenorrhoea and the administration of stilboestrol was recommenced. If prolonged treatment with stilboestrol is contraindicated what alternative is recommended?

**A**—If a psychological effect is excluded—as it can be by substituting inert tablets for the stilboestrol—oestrogens probably relieve dysmenorrhoea only when they are given during the first half of the cycle in a dose sufficiently large to suppress ovulation. Their effect therefore, is limited to the cycle during which they are administered. Although it is not possible to produce concrete evidence, it is reasonable to suppose that prolonged and deliberate disturbance of the ovarian cycle in this way is potentially, if not actually, harmful in a young woman. The writer would therefore advise against sustained oestrogen therapy for dysmenorrhoea. Indeed all forms of hormone therapy generally give unsatisfactory permanent results in this condition.

The treatment depends very much on the cause of the pain. Have psychogenic and environmental factors been excluded? Have active physical exercises been tried? What type of dysmenorrhoea is present—is it congestive or is it of the spasmodic variety? If the latter, antispasmodics might be of some value, but failing that a second and more thorough dilatation of the cervix might be carried out. Hysterosalpingography to exclude malformation of the uterus might be useful. If all else fails and the pain is so severe as to be incapacitating, injection of the pelvic plexus with alcohol or presacral neurectomy should be considered.

Sterilization by Steam

**Q**—What is the correct pressure for steam sterilizing gowns, dressings and gloves? A salesman tells me that 10 lb (4.5 kg) for 35 minutes is absolutely safe and is anxious to sell me a sterilizer to operate at this pressure.

**A**—The deciding factor in sterilization is not pressure but temperature. The temperature of pure steam at 10 lb pressure is 115° C, and this is barely adequate for absolute sterilization. If steam under this pressure is admitted to a closed vessel containing air with no arrangement for displacing the latter, the temperature reached will be only 90° C. If half the air is discharged it will be 105° C. The answer therefore depends on the arrangements for air discharge only if this is complete, the air being blown out by steam before closing and allowing the pressure to rise, could this sterilizer be considered efficient.

## Physiology of Hearing

**Q**—*I have been unable so far to find an authority who can give me any information about the specific gravity of the fluids in the cochlea and their viscosity especially in diseased ears. I would also like references to information about theories of hearing.*

**A**—The perilymph has the same chemico-physical properties as cerebrospinal fluid. No record of analysis of endolymphatic fluid has been found. Modern views on the physiology of hearing may be culled from Stevens, S. S., and Davis, H. (1938), *Hearing: Its Psychology and Physiology* John Wiley and Sons, New York. Fowler, E. P. (1937) *Laryngoscope* 47, 289.

## Congenital Cystic Disease of Pancreas

**Q**—*A child aged 4 suffers from congenital cystic disease of the pancreas. He secretes no pancreatic juice at all. There is also a severe bronchial cough. Pancreatin is given regularly. Has this treatment been proved or not? What is the prognosis? What can be done about the cough?*

**A**—The prognosis at the age of 4 years depends largely on whether the pulmonary complication can be kept under control. If the cough is troublesome it would be advisable to try a course of aerosol penicillin inhalations, 20,000 units in 2 ml normal saline three to five times a day for a week. If this is effective, the same dose night and morning might be continued for another three weeks or according to progress. The invading organism is usually *Staphylococcus aureus* but if not sensitive to penicillin then a sulphonamide or streptomycin might be tried. As there is a danger of converting sensitive organisms to resistant ones it is advisable to stop aerosol treatment during the better periods of the respiratory condition.

Pancreatin improves the stools and seems to aid absorption of food from the gut. Anderson recommends its use, though May has cast doubt upon its clinical efficacy. Anderson considers diet and pancreatin given early in the disease help to prevent pulmonary complications. Usually as the child grows older improvement is observed, and so far cases have been followed up to fifteen years.

## Hartmann's Solution

**Q**—*The Ringer lactate (Hartmann's) solution formerly used for intravenous therapy in infants in this hospital was made up by adding an ampoule of concentrated solution to 480 ml of sterile distilled water and then adding the required amount of glucose solution to make a 5% solution. Our still gives slightly acid water and a small amount of sodium hydroxide was added before autoclaving. The final solution had a pH of about 8.0 (phenol red). Recently we have altered the method and the glucose is added to the water before autoclaving. Because of this we are unable to add the caustic soda as it tends to caramelize the glucose. The final solution now has a pH of 6.2. Will this make any difference or will the lactate be sufficient to buffer this in the blood? Can this solution still be used for the treatment of dehydration whether accompanied by acidosis or alkalosis?*

**A**—The slight acidity of the Hartmann solution will not have any ill effect, and once the lactate is oxidized in the body an ample excess of alkali will be available. It is therefore useful for correcting acidosis but in alkalosis Hartmann's solution should not be used, a simple glucose-saline solution is preferable.

## Injection Treatment of Hydrocele

**Q**—*Are good results obtainable in the treatment of hydrocele by injection with quinine and urethane and is this treatment painless? How does the result compare with operation in a patient aged 56?*

**A**—The injection treatment of hydrocele—carefully carried out—will certainly produce good results but should always be considered a second-best treatment in comparison with operation. This is because incomplete results due to loculation rather than obliteration of the hydrocele sac are by no means uncommon. It would be unwise to promise that the treatment is painless. Reactions vary greatly from patient to patient and are seldom completely absent. If the patient of 56 is otherwise fit he is much better advised to have an operation.

## NOTES AND COMMENTS

**Treatment of "Tennis Elbow"**—Dr JAMES CYRIAN (London W.) writes: Surely the answer to the question on how to treat a 'tennis elbow' (Oct 9, p. 699) is not very helpful. It merely lists a number of treatments to be tried one after the other. In fact, the answer is simple. There are three varieties of 'tennis elbow'. In the commonest (90%) the lesion lies at the lateral humeral epicondyle. For this variety no treatment known to me surpasses Mills's manipulation which even when carried out by our students of physiotherapy at St Thomas's Hospital fully relieves three quarters of all cases within a month. When the lesion lies at the musculo-tendinous junction, deep massage there is usually curative in three weeks. When the lesion lies in the bellies of the extensor muscles, two or three infiltrations with procaine bring about lasting recovery.

**Difficult Delivery**—Dr WALTER McMANN (Dunville, Va., U.S.A.) writes: The answer to the question on this subject (Sept 18, p. 583) seems to evade the question. A baby can present itself by the vertex occipito-anterior, and still be delivered with difficulty. The trouble is that asymmetrism, which is present during the descent of the foetal head, persists after rotation. The sagittal suture, instead of being in the midline, is several degrees to the side, usually left. The occiput is still anterior. Proper application of the forceps means putting them on at an angle so that the sagittal suture is perpendicular to the shank of the forceps. The handles are then brought to the midline by a sideways movement. While an assistant presses just above the symphysis to the opposite side (Willetts's forceps could be used to hold the head in place) the forceps are checked and reapplied if necessary. Extraction follows. Of course a difficult delivery can also be occasioned by the sagittal suture being in the midline and the head deflexed, but from the description given of the forceps marks by the questioner I think this is not the difficulty which has been encountered.

**Transplantation of Ureter into Appendix**—Mr A. H. MORLEY (Surgical Specialist, Tanganyika Territory) writes from Dar es Salaam: In your issue of Aug 7 (p. 321) in reply to a question from the Congo on transplantation of the ureter into the appendix you state that the risks of reflux infection are appreciably increased by reason of the more fluid contents of the caecum as compared with the usual site in the pelvic colon. But is this really so? At the site of anastomosis, wherever it may be, there must be a pool of mixed urine and faeces, and the lower down this is the more highly infected it will be. I had this brought home to me vividly some years ago in a case at the Sewa Haji Hospital. These very large vesico-vaginal fistulae are common in this part of Africa from difficult labour in immature girls in the bush, and when as frequently happens there is an extensive recto-vaginal fistula as well there is a problem indeed. In this case I made the usual examination under an anaesthetic and satisfied myself that the vesico-vaginal fistula was irreparable by me and that there was no recto-vaginal fistula. I then transplanted the ureters into the colon and was dismayed to find that her condition was now worse in that she now leaked both urine and faeces per vaginam. Further examination then showed that she had a very small high recto-vaginal fistula in the posterior fornix, the lumen of which was certainly no greater than that of the ureter and through which a mixture of faeces and urine was pouring.

I have utilized the appendix on one occasion for a unilateral transplant for an operation injury to the right ureter. In this case it seemed to be of advantage in that the patient passed apparently normal motions instead of the two or three watery motions daily which are the usual result of ureter transplants into the colon. It would seem that it can matter little from the point of view of the danger of reflux infection where the anastomosis is made and that the main consideration in the choice of site should be the ease and safety with which the operation can be performed, from this point of view the appendix may have something to recommend it.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 6 1948

## British Medical Association

### PROCEEDINGS OF COUNCIL

Wednesday October 27, 1948

A meeting of the Council was held at B M A House, London, on Oct 27, Dr H Guy Dain presiding

The Chairman extended a welcome to Lord Horder on his first attendance at a Council meeting and to Dr Logan Dahne and Dr R Hale White, who had been elected to fill vacancies

The resignation of Dr J M Hunter, a member of the Council representing constituencies in Northern Ireland, on his appointment to a full-time post under the General Health Services Board was intimated

A letter of greeting was read from the Medical Association of South Africa recently assembled at Pretoria for its annual meeting. The letter spoke of the pleasure with which that Association was looking forward to the South Africa meeting of the British Medical Association in 1951

It was reported that the General Assembly of the World Medical Association had accepted the invitation of the B M A to hold its next annual meeting in London in October, 1949, and that Dr Charles Hill had been elected president-elect

A report of the British Commonwealth Medical Conference held at B M A House in mid-September was presented to the Council. A proposal from the Conference was that, with a view to developing closer personal and professional relations through their national medical units between the nations linked in the Commonwealth a conference of representatives of such units be held once a year in conjunction if possible with a general meeting of the host association, that each country be invited to send two representatives, and that a pooling system be applied for the expenses of one representative from each country. Subject to confirmation, the first conference would be held in Saskatoon in June 1949 at the invitation of the Canadian Medical Association. The Council approved the principle of the proposal and referred it to the Office Committee to look into the question of cost and to report back

#### Proposed Medical Practice Advisory Bureau

The Chairman of Council brought forward a proposal for the establishment by the Association of a Medical Practice Advisory Bureau to provide advice and information to general practitioners and those seeking to enter general practice as locum-tenents assistants or principals, and those seeking hospital and other appointments on the opportunities which exist. The procedure to be followed and associated individual practice problems. He said that he had been impressed by the need for the Association to make evident to its members or intending membership the various fields other than that in which the Association was of service to its members. With the disappearance of sale of practices the work of the British Medical Bureau would cease largely to be lucrative. It was suggested that there was a service which should continue to be provided by the Association should take up this work as an advisory bureau. The directors of the British Medical Bureau had decided that the time would be opportune to set up such a bureau. Any of its servants would be properly

compensated for loss of office, and as far as possible the clerical staff would probably largely be absorbed by the Association in undertaking this new work

Dr E A Gregg and several other members of the Council welcomed the proposal. Dr J C Arthur stressed the need for a regional service, and the Chairman said that it was anticipated that there would be branches in the provinces

The proposal was agreed to unanimously. On a further recommendation that the facilities of the Bureau be available free of charge to members of the Association a charge being made to non-members, Dr Vickers proposed and Dr Waterfield seconded that a small charge be made to all alike, members and non-members, but this amendment was lost. On the other hand, Dr J A Ireland proposed that it be free to all, this was supported by Dr F Gray, but was lost by 19 votes to 23, and the original proposal, with a general plan of arrangements, was approved. It was stated that the new Bureau would be under the general direction of a member of the medical staff of the Association

#### "British Medical Journal"

On the report of the Journal Committee, Dr O C Carter the chairman, proposed that the reduced rate of subscription to the *Journal* which is conceded to students in medical schools in this country should be extended to cover the students of all recognized medical schools in the Commonwealth, provided that no objection was raised by the Medical Associations affiliated to the B M A. This was agreed to

Dr Carter stated that the Committee had carefully considered a memorandum by Dr I H Flack, the Assistant Editor on the possibility of publishing a popular journal concerned with matters of health. A small subcommittee had been set up to pursue the matter further

Discussion took place on methods of making the *Supplement* more useful to members. A view put forward was that all medico political information, reports, and correspondence should be concentrated in the *Supplement*, that some better descriptive name than 'Supplement' might be found, that the *Supplement* should if possible be separate or detachable, and that fuller information should be given concerning any negotiations in progress and any orders or regulations affecting the profession which were issued

Dr Gregg said that there was far more already in the *Supplement* than might be supposed from the comments of some members and he pointed in particular to the exceedingly informative Appendix to the Annual Report of the Insurance Acts Committee (*Supplement* Oct 16, p 138) concerning matters dealt with by the General Practice Subcommittee of the Negotiating Committee. He also mentioned the difficulty of reporting on negotiations while they were in progress, when the premature announcement that a certain point had been gained might actually prevent the subsequent gaining of a better point

Dr Carter mentioned the continuing difficulties arising from paper restriction, but he promised to refer to the Publishing Subcommittee the question of issuing the *Supplement* in a separate or detachable form.

The question of an advertisement recently appearing in the *Journal* from the Birmingham Executive Council was raised by Dr J A Brown. This advertisement required the doctor appointed to live at a certain house in Sheep Street. Dr Beauchamp said that it was not the policy of the Birmingham Executive Council to do this sort of thing, but in point of fact in this area, with which he was well acquainted, there was no accommodation available except the house in question. The advertisement had been referred to him by Headquarters before acceptance, and he took the responsibility. He knew that the advertisement sounded like part of a policy of direction, but it was not.

The Chairman said that the office was evidently exonerated in this instance in view of Dr Beauchamp's explanation, and possibly the publicity given to this matter would prevent its recurrence.

#### Advertising of Proprietary Medicines

A report by the committee concerned with the code of standards relating to proprietary medicine advertising was placed before the Council by Dr Carter. The report was concerned chiefly with a revised code which has been formulated by the Newspaper Proprietors Association and other newspaper and advertising organizations, together with the Proprietary Association of Great Britain (*Journal*, June 19, p 1194). The committee's view was that this code of some 19 classes of advertisements which should be excluded, although only permissive in character, stood a good chance of acceptance and foreshadowed a distinct improvement in proprietary medicine advertising.

It was agreed to reappoint the committee with generous powers of co-option, and to ask it to put forward any amendments to the code to present to the Minister of Health a reasoned statement on the question of the preparation and sale of patent medicines and generally to review the whole position and report back to the Council.

#### Scottish Affairs

Dr G MacFeat, in presenting the report of the Scottish Committee, said that it was proposed to reconstitute the subcommittee which had been working on the subject as the Central Consultants and Specialists Committee (Scotland), its reference being widened to give it power to report not only to the corresponding committee for England and Wales, on which it was directly represented but to its constituent bodies, and to negotiate, within any negotiating machinery that might be laid down, with the Department of Health for Scotland. Dr MacFeat said that a good deal of importance was to be attached to the establishment of this committee, which was regarded as essential if the unity of the profession was to be attained. He hoped that the committee would give some satisfaction to the consultants in Scotland, who had hitherto had very little organization.

In reply to questions by Mr Abel and others it was explained that the committee was composed of representatives from the five Regional Committees of Scotland, to which the staff committees of the hospitals elected representatives. In addition there were representatives from the Scottish Corporations, not however, elected by the Corporations themselves, but nominated by their Presidents or Presidents in Council. The Royal College of Surgeons of Edinburgh had so far not nominated, and another representative was attending only temporarily.

The Council agreed that the Association should accept responsibility for the working expenses of the new committee and gave its approval to the appointment of the Scottish Secretary as secretary of the committee.

Dr MacFeat also brought forward a recommendation that the Scottish Committee be authorized to reopen with the Crown Office negotiations for approval of a revised scale of fees for reports and evidence required by procurators fiscal in Scotland. He said that the proposed scale for attendance at precognitions and for making examinations, conducting inquiries and giving evidence represented a 50% increase on the fees now being received. He asked that the proposal be considered an interim arrangement only until the settlement of fees in England for corresponding services had been accepted.

The recommendation was agreed to, subject to the reservation of the right to reopen negotiations if necessary to bring the fees into line with those obtaining in England and Wales.

#### The New General Medical Services Committee

Dr Gregg moved a recommendation that the designation of the new committee to take the place of the old IAC should be "General Medical Services Committee." Its constitution he said, would be on the same lines as that of the Insurance Acts Committee, but it would be able to review its constitution including the grouping of areas for the election of representatives in the light of experience. It was expected that the new committee would do precisely the same kind of work as the old committee had done, and that it would receive from the Government the same practical recognition.

The recommendation was agreed to. Dr Gregg in reply to a question, said that the constitution could be brought up at the forthcoming "Panel" Conference, but regionalization would not solve the difficulty of areas which felt themselves to be under-represented or not represented at all. This was a question of minority representation, which in the case of a body of 40 or 50 members to cover the entire country was almost insoluble.

#### Remuneration of General Practitioners

Dr Gregg stated that a subcommittee had been appointed to prepare a case for improvement in the remuneration of general medical practitioners, and was meeting on the morrow. In meetings with the Ministry the new committee would follow the practice of the old. A list of matters to be brought forward was kept and if no satisfactory result was arrived at with regard to one of them it was kept on the list and raised again when opportunity offered.

The Chairman of Council said that while a method of remuneration on a basis fair to everybody might not be attainable immediately on the outset of the new Service it was to this end that they were working and no effort was being spared to ensure at the earliest possible moment a result satisfactory to all concerned.

#### Private Patients and Medicines

The question of the provision of medicines and appliances for patients treated privately was spoken to by several members. The Council was reminded that at the Cambridge meeting the representatives expressed the view that those who wished to make private arrangements should not be debarred from obtaining the necessary medicines and appliances through the National Health Service. The view of the Ministry, however, was that prescribing and dispensing were essential parts of treatment and could not be dealt with as though they were something separate. The Ministry also considered that no workable arrangement could be made whereby expensive and life-saving medicines were available for private patients to whom the cost would mean hardship.

Dr Hale White said that if this position were accepted the Association would be condoning the Minister's action in wriggling out of his promise and would also be going back on its own promise to help the general practitioner who was in private practice. Obviously many people were able to afford a private fee to the doctor but not the continuing cost of expensive drugs. The Minister had declared in Parliament that people could take the whole or any part of the Service.

One member suggested that the matter could only be decided in a court of law by a private patient issuing a writ of mandamus, and Dr Gorsky said that the privilege of demanding this part of the comprehensive service was the privilege of the patient not of the doctor, and until a patient took action the profession was powerless.

Dr Gregg said that this was one of the matters on the list of which he had just spoken, and a return would be made to it whenever the opportunity offered. The position of the Government, however, ought to be understood. The difficulty was that there would be no control of any sort over the prescribing of the private doctor. There had been—although rarely—cases of gross carelessness and extravagance in prescribing in the past. Somebody must make inquiry into such matters and how was it possible to ask a doctor for some explanation if he was not in the Service and there was no control over him?

But the question would still be considered and an endeavour made to reach an arrangement which would involve no serious injustice or gross irregularity

The report of the committee was approved

#### Central Consultants and Specialists Committee

Mr A M A Moore, in presenting the report of this committee said that it was now really getting down to its work. By a small majority the committee was opposed to the Spens Committee's suggestion for a system of merit awards, but it had referred this matter to the regions for advice and instruction to their representatives. The committee was anxious to consult the regions at all stages. Mr R L Newell said that he hoped the committee would work together as one body and with all other interested parties, because a united body to express the views of consultants as a whole would be very much needed in the near future.

Dr S Wand pointed out the difficulties under which many young members of the profession were labouring with regard to hospital appointments and questions of accommodation. Dr Pridham raised the question of payment of whole-time members of hospital staffs for domiciliary visits. Mr Moore said that the committee was seeking the advice of the regions on this matter also. The Secretary said that substantial representations had been made to the Ministry on a number of points concerning the position of consultants, including the difficulty of those who found themselves embarrassed with regard to their financial obligations as a result of the working of the provisional scheme of remuneration and the virtual disappearance of their private practice. He understood that the Specialist Spens Report had raised wider questions bearing on national expenditure concerning university teachers and others in fields outside medicine.

#### The General Practice Committee

On the recommendation of the General Practice Committee the Council agreed to inform the War Office that in the view of the Association it was both practicable and desirable to make arrangements for the medical examination of recruits to the Territorial Army by medical boards, and the Department was urged to establish such boards without delay. The view was also expressed that where it was impracticable to arrange for the medical examination of a recruit by a medical board the scope of the examination was now so wide as to justify a fee of 14 guineas for the examination and report when carried out by a single practitioner. Failing the adoption of these proposals by the War Office members of the profession are to be advised not to undertake the work of examining Territorial Army recruits.

Among the many other matters set out in the report of the General Practice Committee was the question of doctors' signs on cars as to which the committee took the view that there appeared to be no necessity for such distinguishing signs.

Mr Dickson Wright and Lord Horder took a different view. Mr Horder said that while it was true that the sign might be abused doctors should have some privilege in this respect in the public interest. A very modest sign on the windscreen might attract the attention of the police, who were usually sympathetic so that they would allow the car to pass if it should be at the end of a queue.

It was agreed that this matter should be looked into again.

#### Membership of the Association

In presenting the report of the Organization Committee Mr Pridham said that the membership of the Association had for the first time touched 60,000.

Concerning the new Dominions in the East his committee had received an Indian Medical Association proposal for a separate medical bodies. They had been informed that the Indian Medical Association was in process of formation but had not proceeded far enough for approaches to be made. The Ceylon Branch which comprised 10 per cent of the Association should be changed now that Ceylon had become a Dominion and it desired that its future should be decided by the Ceylon Medical Association. Nevertheless it should remain an integral part of the Association.

and to become an incorporated body. The Organization Committee was advising the Branch on the steps it should take in the matter.

Dr Pridham reported that the committee had given careful consideration to proposals of the Winchester Division for reorganization of the constitution of the Association, which had aroused considerable interest. The Division had accepted an invitation to send representatives to discuss its proposals at the next meeting of the committee. The committee contemplates reporting on the whole matter to the Council in January.

#### Ethical Business

It was reported that the Medical Association of South Africa which had found it necessary to ask its members not to accept appointments under the Provincial Hospitals Ordinance (Transvaal), 1946, had requested that the attention of practitioners in the United Kingdom should be drawn to the fact that they could materially assist their colleagues in South Africa by not applying for such posts. The Central Ethical Committee considered that the circumstances were such as to justify an 'Important Notice,' but in view of the recent change in status of the Medical Association of South Africa this involved an amendment of regulations. It was therefore proposed that the regulations relative to the insertion of such notices be amended to provide that if the chairman of the Central Ethical Committee was satisfied that the information justified such a course such notices might be inserted upon application of the Medical Secretary of the Medical Association of South Africa (or of the General Secretary of the Canadian Medical Association). This was agreed to.

Another recommendation from the committee, which was approved, was that in advising patients referred for consultation, including those referred for examination under the Supplementary Ophthalmic Service, the general practitioner was acting in accordance with the recognized ethical custom of the profession in recommending to the patient the particular specialist whom he regarded as best fitted to provide the service required.

#### Port Medical Officers

On the report of the Public Health Committee which was presented by the acting chairman Dr R H H Jolly, the question arose of a scheme proposed by the Bristol Corporation and the National Dock Labour Board whereby two whole-time port medical officers employed by the Corporation were permitted to carry on private practice to such an extent as to enable them to make a personal contract with the Dock Labour Board to act as medical officers in an accident and first-aid scheme. The matter had been raised by the Bristol Division, and the Public Health Committee, after a lengthy consideration of the local circumstances, passed it on, with comments, for the information of the Occupational Health Committee. It was stated that the Dock Labour Board had refused to advertise these appointments. Although it appeared that the arrangement was now an accomplished fact and nothing very useful could be done in this particular matter, which had certain exceptional aspects, it was agreed that a protest should be forwarded to the proper quarter with an expression of the hope that such arrangements would not be repeated in the future.

#### Women Medical Officers in the Armed Forces

Sir Percy Tomlinson, chairman of the Armed Forces Committee, made a statement on the question of equal status for women medical officers in the armed services. This principle of equal status had been strongly affirmed by the Medical Women's Federation whose resolutions on the subject had been supported by the Annual Representative Meeting 1947. The view of the Armed Forces Committee, however, was that the Federation should not be supported in its representations to the Government on this matter, and it asked the Council to rescind a resolution of its own, passed in June, 1947, stating that it was prepared to support the Federation.

The Council agreed that the Medical Women's Federation should have an opportunity of studying Sir Percy Tomlinson's statement and that the matter be deferred to the next Council meeting, which would have before it both Sir Percy's statement and the reply.

**Association Finance**

The Treasurer (Mr A M A Moore) presented a financial statement covering the Association's accounts from May to August. He pointed out that, although income had risen expenditure had risen at a greater ratio but many items of expenditure were non-recurring—for example it was hoped that in future it would not be necessary to have four Representative Meetings in one year. Dr Wand suggested that a budget for the next financial year should be prepared well in advance and that with it there should be circulated a statement of the case for an increased subscription from Jan 1, 1950.

**Miscellaneous Business**

The Arrangements Committee submitted an early programme for the scientific part of the Harrogate Meeting, 1949. It proposed that the meetings of Sections should cover four days instead of three, and should begin on the Tuesday. This proposal was favoured by the Council. Dr Gorsky urged the creation of a Section of Forensic Medicine and Dr Wand a Section of General Practice, and these were noted for the meeting of 1950.

The report of the Building Committee, presented by Mr L. Dougal Callander, stated that the redecoration of the basement garage at Headquarters was practically completed and would afford accommodation for the parking of up to 60 cars.

On the proposal of Dr R G Gordon chairman of the Science Committee, the subjects of the essays for Association prizes for 1949 were agreed to and the Science Committee's proposal that the Association should become a contributing member of the British Standards Institution was also accepted.

The report of the Committee on Nursing was presented by Dr Mary Esslemont. It contained proposals for nursing legislation, as yet confidential, to be presented to the Government. The Chairman of Council expressed great appreciation of the work of this committee, and said that the document before them was probably the best that had ever appeared on the subject of nursing, not even excepting the report of the Working Party.

Reports from the Occupational Health Committee, the Colonies and Dependencies Committee, the Health Centre Committee, and the Committee on Psychiatry and the Law were adopted without discussion.

The Council agreed to continue the work of the Central Medical War Committee provided the Ministry of Health continued its contribution towards the expenses.

A letter and resolution from the Winchester Division on the question of the Maternity Regulations under the National Health Service Act were after consideration referred to the General Medical Services Committee.

The Secretary made a report on a proposed Joint Consultative Committee of professional bodies to facilitate exchange of views on matters of common interest. The proposal commended itself to the Council.

The final matter which then came before the Council was taken out of the Chairman's hands by the Treasurer, Mr Moore who proposed that arrangements be made for the painting of Dr Dain's portrait the cost to be borne from Association funds. This was put to the Council by the Treasurer and unanimously and with acclamation approved.

The Council, which began its meeting at 10 a.m., concluded its business at 6.15 p.m.

**TRADE UNION MEMBERSHIP**

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar.

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend.

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Hutton-with-Roby, Redditch (restricted to new appointments), Tivdlesley.

**WORK AND INCOME****A REPORT FOR THE MINISTRY**

The British Medical Association is gravely disturbed by reports reaching it from all parts of the country of the effect of the new Health Service on the work and income of doctors. It is clear that as a result of the Act there are many doctors who are overwhelmed with work because of the greatly increased public demand. In spite of doctors being fully occupied many of them are finding it impossible to meet their commitments. The Association is preparing a report on the whole position for presentation to the Minister of Health and the Secretary of State for Scotland.

**MEDICAL PRACTICES ADVISORY BUREAU  
HELP FOR THOSE SEEKING APPOINTMENTS**

The Council at its meeting on Oct 27 approved in principle the establishment of a Medical Practices Advisory Bureau to provide advice and assistance to medical practitioners, including those seeking to enter practice as locum assistants, or principals and those seeking hospital and other appointments on the opportunities which exist, how they should be followed up and associated individual practice problems.

It was agreed that the services of the Bureau, which would include an Appointments Information Service, should be free of charge to members of the Association and available to non-members on payment of appropriate fees. The B.M.A. appreciates that the need for these services is pressing and will put the scheme into effect as soon as possible. Further announcements will be made in due course.

**REMUNERATION OF HOSPITAL STAFFS  
CONSIDERABLE HARDSHIP**

The Association is seriously concerned at the present financial position of many members, both senior and junior of hospital staffs. The £1,600 ceiling on the remuneration of specialists is causing considerable hardship in many cases and junior residents whose salaries were always low, have been seriously hit by the new compulsory deduction of National Insurance and superannuation contributions. The Ministry of Health's statement that present salaries are merely a payment on account is no consolation to a specialist or an ex-Service married house physician who is rapidly getting into debt. Action to relieve hardship in these categories is urgently needed.

**COMPENSATION UNDER N.H.S.  
CLAIMS DELAYED**

Oct 31 was the last day by which claims for compensation should have been in the hands of the Ministry except where delay was unavoidable. Any claim now submitted should be accompanied by a statement of the reason for the delay. The Practices Compensation Committee has begun its task. Its composition is as follows.

Chairman: Mr P M Rees M.C. F.C.A., Member of the Council of the Institute of Chartered Accountants.  
Members: Dr G F Buchan (London), Dr W Jope (Lancashire), Dr S Wand (Birmingham), Mr O E Tattersall (Twickenham).

The regulations provide for a joint secretariat and one of the assistant secretaries of the Association has been appointed to act jointly with the secretary appointed by the Minister. Individual members of the Committee cannot undertake to answer correspondence. Names of claimants are not divulged to members of the Committee all cases being dealt with under serial numbers. Information submitted with the claim is of course regarded as strictly confidential. Claims for early payment of the whole or part of the compensation due may be made at any time. Full details in support of the request should be given.

## URGENT PROBLEMS OF SPECIALISTS

### DISCUSSIONS WITH MINISTRY

Among the problems disturbing specialists and consultants at the moment are the following

*The gross inadequacy of the mileage allowance*—From information collected it is clear that the Government's figure of 6d per mile by no means covers the cost of running a car, still less the cost of the time spent in travelling. Transferred whole time salaried specialists who previously received basic car allowances have been severely penalized by the withdrawal of these allowances.

*The unsatisfactory position of medical superintendents*—Evidence continues to be received that the authority and status of medical superintendents are being deliberately undermined.

All these matters are being discussed with the Ministry. It is strongly felt also that there should be no limitation on the number of domiciliary visits in a quarter, that consultants should not be penalized by receiving no payment for visits to patients in nursing-homes, and that additional fees should be payable to anaesthetists, radiologists, and cardiologists to reimburse them for expenditure on apparatus and materials. The interpretation of the "half-day" needs to be better defined with greater regard paid to the length of time occupied in the ward round or session.

The whole scope of the National Health Service as it affects specialists must be defined better. The Interim Terms of Service lay down that the fees for professional work not forming part of the duties performed for the regional hospital board or board of governors may be retained. The question is, What professional work is not a duty performed for the board? Does it include examination of cases referred by medical officers of the armed Forces or by the Ministry of Pensions and the radiographic examination of emigrants demanded by the Canadian and Australian Governments? These questions have been taken up with the Ministry.

### GRANTS FOR TRAINING ASSISTANTS SOME DEDUCTIONS

Those interested in the scheme of grants for training assistants (*Supplement* Oct 30, p 149) will have noticed that apart from the car allowance the amount available for the assistant's salary and expenses will, in effect, be under £640 a year, for the principal will have to pay something like £67 a year in employers' contributions for national insurance and superannuation in respect of the trainee assistant. Similarly, the trainee assistant will pay a superannuation contribution of 6% of his salary and of course, the national insurance contribution of 4s 11d a week. In addition, the principal pays his own superannuation contributions at 6% on the whole of the £150 training grant he receives, the employers' share of 8% of the same amount being borne by the executive council. The Association has pointed out to the Ministry that no hint of these deductions was given when the announcement first appeared.

### CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE

#### AN AUTONOMOUS BODY

There is some misunderstanding about the status of the Central Consultants and Specialists Committee. It may be partly due to the wording of Minute 71 of the Representative Body (see *Supplement* July 3 p 10), which, after providing that the Committee shall be an autonomous body, states that the decisions of the Committee shall not be subject to approval of the Council or the Representative Body *except so far as they may affect other forms of practice or other aspects of the policy or activities of the Association*. Some have felt that this proviso may undermine the autonomy of the Committee but in fact its only effect is to limit the autonomy of the Committee to its own sphere of interest. In matters relating to specialist practice the Committee is completely autonomous. Its members are nominated chiefly by the Regional Consultants and Specialists Committees and representation is open to non-members of the Association and to members.

To remove any doubts about the Committee's autonomy, the Council is being asked to recommend to the Representative Body that the minute be amended to express more clearly the wishes of consultants and specialists.

How the various bodies shall operate is now being discussed with the Royal Colleges and Corporations, and also what liaison is necessary to provide one channel for presenting the views of consultants and specialists to the Minister of Health. These discussions in no way infringe the autonomy of the Central Committee. Whatever liaison is ultimately brought into being, the Committee has a unique part to play. The better it is supported the more effective will be that role.

### SCHOOL EYE CLINICS METHOD OF PAYMENT

Revised arrangements for the remuneration of medical practitioners in school eye clinics have been announced by the Ministry of Education. The fee will be 6 guineas for a session of three hours and a proportionately lower fee for sessions normally of shorter duration. The medical practitioner (if his name is entered on the local ophthalmic list) will also be entitled to a payment from the local executive council of 12s 6d per sight-test, which he will be required to hand over to the local education authority responsible for paying his sessional fee. Alternatively, he may give instructions to the executive council to pay the 12s 6d per sight test direct to the local education authority. The existing mileage payments which are made by local education authorities for travelling to school eye clinics will remain for the time being unaltered.

It is apparently not universally known that Form O S C 2 may be used by practitioners whose names are not included in the local ophthalmic list to prescribe glasses for children at school eye clinics. In such cases the local education authority will not be entitled to the payment of 12s 6d per case from the executive council.

It is understood that neither the Ministry of Education nor the Ministry of Health has issued any instruction to local education authorities discouraging the attendance of children under 5 at school eye clinics.

The transfer of school eye clinics to the control of regional hospital boards will begin shortly and should be completed within a year. When complete school oculists will probably be remunerated by regional hospital boards in the same manner as specialists—for example, by annual salary.

### ARMED FORCES AND C.M.S.

The Armed Forces Committee has started reviewing the remuneration of Service medical officers in the light of the recommendations of the two Spens Reports, and the Colonies and Dependencies Committee has begun the same task for the Colonial Medical Service.

### REPORTING INQUESTS ON SUICIDES

The B.M.A.'s proposal that the report of an inquest on a suicide should be limited to the fact of the inquest, the name and address of the deceased, and the verdict was condemned at the annual meeting recently of the Guild of British Newspaper Editors. The meeting passed a resolution approving discretion in the reporting of such cases but stating that the limits suggested by the B.M.A. "would suppress information of great public value and would thereby hinder justice and reform". The matter was discussed at the A.R.M. on June 29, when Representatives made it clear that, in the words of one of them "the last thing they desired was to interfere with Press freedom" but evidence was shown that the reporting of intimate details in these cases was often painful to the relatives and had on occasions brought about imitative suicides.

Authorities granted by the regulations made under the Dangerous Drugs Act, 1920, have been restored by the Home Office to John Stuart Prentice, M.B., Ch.B.

## National Health Service News

### Remuneration of General Practitioners

General practitioners will be paid on account for the period Oct 1 to Dec 31 on the same basis as they were paid for July 5 to Sept 30, states the Ministry of Health. It has accordingly asked local executive councils to inform the Minister not later than Nov 6 of the total number of forms EC1 received up to and including Oct 30. The Ministry points out that the figures submitted by executive councils of the number of these forms received by July 31 were in many cases only estimates with the result that there was a substantial measure of inflation. It emphasizes that it is important that the forms should now actually be counted. The Ministry hopes to notify executive councils early in December of the amounts available for distribution to doctors.

### Berkshire Local Medical Committee

The Berkshire Local Medical Committee has decided to send a short report of the matters discussed at its meetings to all medical men in the county in order to keep them informed of current events.

### Lay Officers to Sign Certificates

The Ministry of Health states that intermediate medical certificates for hospital inpatients may be signed by a lay officer to relieve the burden on the medical staff of hospitals. The Ministry of National Insurance will prepare the two certificates, which will be known as Med 7 for short-stay patients and Med 8 for long stay patients. Local executive councils will distribute these certificates.

## THE ASSOCIATION AND PUBLIC HEALTH

A meeting of the Public Health Committee of the Association was held on Oct 8. It was reported that Dr James Fenton, the chairman who has been seriously ill, was improving in health and was hoping to take up his active work again before very long. The Committee re-elected him to the chair and appointed Dr R. H. H. Jolly acting chairman until Dr Fenton should be able to resume.

A resolution from the Annual Representative Meeting calling attention to the inadequacy of the percentage increases in the salaries of whole time medical officers of health was considered. It was stated to be the desire of the Ministry of Health that, as soon as the general principles concerning the Whitley machinery had been agreed, the public health part of that machinery should be brought into operation.

On the subject of the present position regarding the production and distribution of milk and of other foods of animal origin it was decided to approach the National Veterinary Medical Association with a view to setting up a joint committee to investigate the matter and ultimately to go to the Ministries concerned in this question. A letter was read from the Ministry of Health expressing full appreciation of the Committee's view that local authorities should be advised of changes in the milk regulations prior to or simultaneously with the issue of any public announcement and regret was expressed that in a recent instance a letter addressed to medical officers of health announcing such a change was not issued earlier.

A resolution from the A.R.M. calling for the frequent reconsideration of the question of compulsory vaccination was noted. It was the feeling of the Committee that it would be in a better position to make representations on the subject when the results of voluntary vaccination were more fully known.

Another resolution expressed the view that it should not be part of the duties of the public health staff to examine municipal employees for superannuation. It was pointed out that the Association's policy in this respect was laid down in 1936, when it deprecated the increasing tendency for the employment by municipal authorities of part-time and salaried medical

officers not engaged in private practice for the performance of clinical work which was within the private practice sphere. A year ago in relation to a particular case the Committee stated that it was contrary to Association policy for medical officers of health to be required to undertake the medical examination of employees but considered it inadvisable at the moment in relation to the particular case to press the point.

Considerable time was spent over a similar question relating to port medical officers. This arose over a case at Bristol where the National Dock Labour Board—a federation of representatives of employers and employees in all ports—and the Bristol City Council have arranged for two port medical officers to be available to the Board for part of their time in connexion with an accident and first aid scheme in the dock area. The view of the Committee was that it was undesirable that men who are full time servants of one authority should be farmed out with another for part time work. It was pointed out however that there were peculiar circumstances at Bristol which have been explored by a deputation from the Association to the authorities concerned. The Avonmouth docks where the service is rendered, are in fact owned by the Bristol Corporation. While the National Dock Labour Board's general policy is to appoint whole time medical officers under its direction the Bristol dock scheme is not considered large enough to justify such an appointment. In the circumstances which were quite special to the area, the Committee agreed not to take further action on the understanding that the remuneration in respect of accident and first-aid work should be regarded as additional remuneration.

It was agreed that at the earliest reasonable moment negotiations should be opened with the local authority associations on fees for service to local authorities which have not hitherto been negotiated. These include fees for a wide range of services set out under eleven headings in a document placed before the Committee.

A report was received on representations made by the Committee and the Society of Medical Officers of Health on the Children Act, 1948. Certain minor amendments only were made in the sections which had been the subject of representations by a deputation from the Committee.

### HOUSE PURCHASE LOANS IN SCOTLAND

The Medical Insurance Agency has completed arrangements for providing financial assistance for young general practitioners entering the National Health Service in Scotland. In approved cases 100% of the valuation of house property can be advanced, together with a sum not exceeding £500 for equipment. Full details will be supplied on application to the Medical Insurance Agency, British Medical Association House 6 Drumsheugh Gardens, Edinburgh 3.

## HEARD AT HEADQUARTERS

### Science at Harrogate

The Harrogate Meeting in 1949 looks like having more scientific discussion than ever before. Within living memory three days have been devoted to the Sections but at Harrogate it is proposed to have four days. There will be 18 Sections in all four of them meeting on all four days, 10 of them on two days, and the remainder on one day. When the Sections were first instituted in 1867, they numbered only four—medicine, physiology, surgery and midwifery. Ten of the Section presidents will be from the West Riding.

### Are Doctors Civil Servants?

When application was made in the King's Bench Division recently to fix a date for the hearing of an accident case convenient to three medical witnesses it was said that doctors are now 'Civil Servants or public servants'. In refusing the application Mr Justice Hilbery said that as four fifths of the

population were rapidly becoming Civil Servants nowadays they would get nowhere if he granted it. If I fix a date because of the difficulties of these professional men, I should have to fix a date for all professional men who are incommode by having to come to court on a day which upsets all their arrangements. Nearly everyone is a Civil Servant nowadays. How many millions are there?" Since there are commonly said to be about two million, he may have felt some alarm at the threatened dislocation of the court's business. But many doctors may wonder whether the demands made on them by the sick should be put in the same category as those made on Civil Servants.

#### Much in a Name

When the retiring President of the Medical Society of London, Mr W E Tanner, vacated the chair the other evening he introduced his successor with the full medical flavour of his name—Dr Theophilus Jenner Hooper Hoskin. The portraits of Jenner and Hooper, both of them outstanding figures in the early history of the Medical Society, were on the wall behind him. The "most noble Theophilus" was the person to whom the beloved physician St. Luke dedicated his Gospel, while Hoskin, the surname, had a medical significance before Dr Jenner Hoskin gave it further distinction for his father is still remembered as a well-known London physician.

#### Tributes

Though the Council of the Association spent a long day mostly looking to the future, it did not forget to honour the past. It warmly endorsed a tribute paid by the General Practice Committee to Dr J W Bone, who, for part of the time as chairman, has served that committee for 25 years, and a similar tribute by the Finance Committee to Dr Bone's outstanding services as Treasurer of the Association. The Central Ethical Committee also said a regretful good-bye to Dr N E Waterfield as chairman, he still remains a member of the committee. Finally, the Council agreed unanimously that Dr Dain's portrait should be painted at the expense of the Association, but this does not signify the end of Dr Dain's service to the Association, although he has intimated that this will be his last year in the chair.

#### The Bill Comes In

It is a good answer to those who prophesied a large number of resignations that at the end of October the membership for the first time touched 60,000, with five to spare, a gain of 2,000 during the last seven months. The revenue of the Association also is increasing, but the Treasurer has given a salutary reminder that expenditure has a tendency to increase at an even greater rate. Special Representative Meetings one after the other are important affairs, but they are costly ones too, each of them running into something like £1,000. Plebiscites, too, are not taken for nothing, and public relations and similar activities, while very fruitful, swell the bill. There are hints of an increase in the Association subscription from 1950. If that does come to pass it will only be in line with the course taken by societies and institutions of all sorts representing all professions and interests.

#### Occupational Health Abroad

The Occupational Health Committee some time ago asked for information about schemes of occupational health in foreign countries. Inquiries were made of the embassies of the United States and Brazil and of nine European countries. From the United States, Belgium, Norway, Switzerland, and Denmark full information has been forthcoming. The Soviet Embassy forwarded a copy of the constitution of the USSR and documents on public health, accident prevention and Soviet health protection in peace and war. Sweden, misunderstanding the request, sent particulars only about insurance. There has been no response from the others, yet the recent International Congress on Industrial Medicine in London showed what active occupational health work is being done in Czechoslovakia, the Netherlands and other countries.

#### Solving the Nursing Problem

The Association Committee on Nursing is very active, although much of its work, such as representations to the Government, must remain for the time being confidential. Under Dr Mary Esslemont, it has completed its discussion of the problem of obtaining more nurses through reformed methods of training and is now considering how the available force of skilled nurses may be used to the best advantage. Economy in the use of trained nurses is probably as necessary as bringing in new recruits. Incidentally, at the recent Nursing Conference held at Seymour Hall, London, the number of male nurses attending was remarkable. They came not from mental hospitals alone but from special hospitals such as urological centres.

## Correspondence

#### Basic Salary

SIR,—Apart from any other consideration, I joined the National Health Service in July in response to the express wishes of two junior partners. At that time the only official correspondence in my possession in regard to the scheme of payment for doctors under the Service which I had received consisted of a double sheet entitled "Remuneration of General Practitioners," issued by the Ministry of Health in April and the regulations of the Health Service entitled "Statutory Instruments, 1948 No 506." In the first of these it is stated that the fixed annual payment of £300 is open to any principal at his choice, while the second states as the first item of remuneration of practitioners "the fixed annual payment of £300." It was obvious to me having conducted a private middle class practice for nearly 30 years that my income would suffer severely under the new Service, and I therefore notified the Clerk of the London Executive Council at the time of entering the Service, that I wished to be remunerated under the system which would give me in the first place a fixed annual payment of £300.

On Oct 1 I received a cheque from the London Executive Council without any reference to payment of the fixed annual payment, and I therefore communicated with the clerk of the council to ascertain why my request in that matter had not been met.

On Oct 7 I received a circular letter from the clerk of the council in which he informed me that the fixed salary of £300 was no longer to be the option of any practitioner that it was only to be given at the discretion of the council and that the council would give its consent only in cases where there is reasonable justification for so doing. He went on to explain that reasonable justification included any case where a practitioner's income could be shown to have dropped substantially as a result of the new Service. He also went on to say that the council and the local medical committee would require to be completely satisfied that such justification exists. He finally wrote that if the grounds of my application were that my income had fallen it would be of assistance if I would supply information with regard to the amount of income at present derived by me "from professional and other sources."

On Oct 11 I wrote to the clerk of the council recapitulating the information in my possession at the time I joined the Service in regard to the remuneration of practitioners. I pointed out that I had received no notification that the terms which had been published had been altered and that I had not been consulted in regard to this unilateral alteration of these terms. I ended my letter by giving notice of my resignation from the Service as from March 31 next year.

On Oct 14 I received a letter from the clerk of the council acknowledging my letter of resignation. He said "It is impossible for me to say at the moment what information will be required in connexion with an application of this kind." I replied on the same date to the clerk of the council saying that his statement amazed me, considering the fact that on Oct 6 he had written asking me for information with regard to the amount of income at present derived by me "from professional and other sources."

I have had no further communication from the council, and I am therefore left to assume that the Minister of Health is free to seek my service under the National Health Act by offering me a contract regarding my remuneration for that service which he has not the slightest intention of honouring.

This surely is a useful illustration of the new meaning of the word freedom as now understood in a Socialist democracy—I am, etc.,

London S.E.24

KENNETH MCFADYEAN

SIR,—Local medical committees have recently had the invidious task of advising executive councils as to which applications for the £300 fixed annual payment should be granted. Among the considerations which weighed heavily with these committees has been the fact that each payment of the basic salary reduces the sum available for all other practitioners in the area. Many rejected claims would have been approved had the money been derived from some other source than the local pool. One chairman of committee stated that all the claims would have been approved in such circumstances. Nearly one third of the practitioners in the area concerned had applied for the fixed annual payment.

The logical inference is that had the Minister offered an optional basic salary in addition to the capitation pool it would have been generally acceptable. What a long way from the principle of no salary element in National Health Service! A demand for higher remuneration for practitioners is rapidly gaining impetus. An increase may be offered to the Negotiating Body in the form of a basic salary in addition to the existing central pool. Have our negotiators now any grounds for believing that such an offer would be unacceptable to the profession?—I am, etc.

Worcester Park, Surrey

R. V. GOODLIFFE

SIR—Two matters which seem to be exercising the minds of your readers at present are the failure of the B.M.A. to stick to its guns in the matter of joining the National Health Service, and the recent cold douche so many received along with their first cheque. May I as one who resigned from the B.M.A. because of what I conceived to be a foolish and unrealistic policy pursued by misrepresentation and supported in the main by those who (1) disliked the Labour Government (2) disliked Mr. Bevan, and (3) disliked change, comment on the above points?

While I believe there was too much inspiration against the Act from the Headquarters of the B.M.A., I consider nevertheless that B.M.A. policy did truly represent the views of the profession as evidenced by resolutions passed at Branch meetings and so the members who voted for these resolutions have little reason to complain now if the cheques they have recently received are not so large as they expected. They insisted on resistance to the Act rather than thrash out the details in good time. I agree, however, that we were led to suppose we should receive a basic salary of £300 per annum *plus* a capitation fee of 15s. 6d. to 18s., and we naturally supposed that if we did not elect to receive the basic salary we should get a correspondingly larger capitation fee. Instead we find a capitation fee of about 16s. reduced by one seventh if we are permitted the basic salary. The net result is that many are rather worse off than if all their patients had been put on the panel under the old arrangement.

To sum up in my opinion the B.M.A. is suffering from some unjustified mud-slinging and the profession as a whole has been let down by the Ministry while blindly looking for wood amidst the trees—I am, etc.

Ridgmond, Yorks

### Opticians and Home Visiting

SIR—A patient of mine who is above 70 years of age and an invalid needs glasses. I gave her Form OSC1 and suggested that the optician should visit her to change the glasses. The optician refused to come and on inquiry with the executive committee I find that they cannot compel any optician to see the patient at her home, and furthermore if any optician agrees to do so the patient will have to bear the expenses. Obviously the patient can only go to the optician in an

ambulance or an invalid conveyance. To me it sounds ridiculous that a doctor, who is paid 3½d. a week has to visit the patient every time and an optician who I believe is paid 15s. 6d. for sight testing and is at the moment making about £120 (authentic information) per week, has no obligation to see an invalid at her home. This is our so-called comprehensive service. Personally I think that nothing can be more ridiculous—I am, etc.,

### Domiciliary Treatment of Obstetric Emergencies

SIR,—At a recent meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine the value of some form of 'flying squad' for the domiciliary treatment of obstetric emergencies was clearly illustrated. Reports from many parts of the country showed that the number of calls for such service are increasing each year, as are the number of maternal lives saved. Most speakers agreed that the efficiency of the service depended on the presence of an experienced obstetrician on the spot.

I would like to draw attention to the fact that the present rate of payment to consultants for domiciliary consultations under the National Health Service constitutes a serious setback to the further development of such schemes. In many cases the payment is even less than that previously paid by the local health authorities. When long distances have to be covered and half a day or night may be occupied in dealing with such cases a fee of 4 guineas plus 6d. a mile will hardly encourage suitably experienced persons to undertake the work. If a larger fee is payable for major treatment in the home (which is often to the advantage of the patient and saves valuable hospital beds) there is a corresponding reduction in the number of cases for which payment will be made in any one quarter.

If the standard of obstetric practice in the country is to be raised the drop in maternal mortality maintained, and the unnecessary use of hospital maternity beds avoided there is surely an urgent need for the revision of the rates of payment to consultants for domiciliary service—I am, etc.

A. P. BENTALL,  
Chairman of the Obstetric Committee  
Norfolk Executive Council

Norwich

### Cambridge Meeting Guarantors

SIR—When it was first decided to hold the 1948 meeting of the British Medical Association in Cambridge the customary practice was followed of getting the local medical men to become guarantors of £5 5s. towards any possible loss. I am now notified by Dr. F. A. Grange, the Secretary of the Finance Subcommittee here, that B.M.A. Headquarters have decided to abolish the guarantee and that no call will be made upon the guarantors.

I shall be grateful if you will kindly publish this announcement, mainly for the information of those concerned but also because it gives me an opportunity of expressing Cambridge appreciation to their visiting colleagues who paid their registration fee, as well as to Headquarters for relieving them of financial responsibility for the meeting—I am, etc.

R. SALISBURY WOODS  
Hon. Local General Secretary  
B.M.A. Meeting 1948

Cambridge

### Representation of Civil Service M.O.s

SIR—Has not Civil Service M.O. (Supplement Oct. 9 p. 134) overlooked the fact that the Institution of Professional Civil Servants is the body duly recognized as the responsible negotiating body for the medical officers as well as other professional officers, in the Civil Service? The Institution's medical panel is a very active body and has already given notice to the Treasury that the pay scales of the Civil Service M.O.s need adjustment in the light of the Spens Reports. The medical panel is now engaged in drawing up details of its claim, based on the Spens Report, and it goes without saying that in this matter the Institution keeps in touch with the B.M.A.—I am, etc.,

STANLEY MOYNE  
Gen. Secy

Institution of Professional Civil Servants

### Age Limit for Practice

SIR—I enclose a letter which I received two days ago. The subject matter is not of other than local interest, except for one paragraph, the second. There it states that according to our records you are already beyond the age limit which is being considered in connexion with this service, and I regret that when the service is functioning fully, I may be unable to avail myself of your assistance. Meanwhile please carry on until you are formally fired.

Everybody realizes that there is a great shortage of medical men. Every doctor realizes that the new Health Service will make that shortage stand out in high relief, yet we have a Government Department announcing that it is proposed to adopt an arbitrary age limit without reference whatever to efficiency. The action is the more illogical since general practice under the Health Ministry has no age limit.

I am a long way past the age limit—I know what it is—but I hold the (unpaid) chairmanship of two rather important Ministry of Labour Committees without any noticeable display of senility. Is not this a matter that the B.M.A. might well consider? You will notice that the letter is cyclostyled. There must be quite a number of us dodderers—I am, etc.,

Salford Lancs

STANLEY HODGSON

### Partnerships

SIR—Many partnerships will view with dismay the proposals which form the basis of the memorandum submitted on behalf of the profession to the legal committee on partnerships appointed by the Minister. So many partners count their capital assets in terms of valuable options as well as in the actual shares they held on the appointed day. It is of course right that the buying and selling of these options should be discontinued, although apparently that is still permissible under the present form of the Act. Such buying and selling is not only contrary to the general ban on such business imposed on all individuals who entered the Health Service but it may often involve a partner in the compulsory purchase of some share in a partnership the value and availability of which have been entirely changed because the Act came into force. On the other hand in a large number of cases it would be grossly unjust to deprive a partner of capital ownership to which he was entitled and which he had to some extent already bought. It is not clear whether the recommendation to stop the exercise of options etc. merely forbids the passage of money pending final settlement or whether this clause taken in conjunction with the next one tying compensation to the actual shares held by partners on the appointed day, is to be taken to mean that capital assets not actually held as such on the appointed day will be just rubbed out. If that is what is really intended, however liberal compensation may be, scores of partners are going to be very harshly dealt with.

Take the usual case of a junior partner. He often pays for a small share in the partnership and expects to do a large share in the work, increasing the total value of all the partners' shares by bringing to bear all his youthful enthusiasm and energy with a fund of up-to-date knowledge. If he is very green and has no previous experience of general practice it may be argued that this is all worth while for the experience and such guidance as a senior partner can offer. In actual fact that is seldom the case and most junior partners are not called upon to accept the position for such intangible rewards. It is in fact the rule for their agreements to specify that they will be definite stages or on partners' retirements succeed to greater rewards for their early labours for the common weal. They have at least the option to purchase at these junctures some of the shares held by the senior partner or partners, thereby enjoying henceforth a correspondingly greater share of the income and acquiring legally a right over capital they have already earned morally.

The price paid is fixed at the time the original agreement between the partners is drawn up in the full knowledge and expectation that the new partner by dint of his own labours, may increase the sale value of this share beyond that price. Prospects of that sort are a very real and most important consideration for what is paid down by an incoming partner and any law which deprives him of these is most unjust, especially if it intervenes after the junior partner has nearly completed the period of hard work for disproportionately little remuneration.

Surely he will not be frozen permanently in this position. One hopes that he will remain sufficiently liberated in future

to enjoy at least as much as he now earns, even if he has lost for ever all prospect of enjoying anything more than that when he takes a junior partner. But what of the share capital he should now be entitled to acquire at the initially agreed price? At present it is, and was on the appointed day, part of the senior partner's holding and may be included in the senior partner's claim for compensation. To say no more of the income is not the junior partner at least entitled to claim compensation for loss of whatever difference there may have developed between the agreed price of this share and whatever will eventually be paid to the senior partner by way of compensation for that gentleman's loss of the right (or rather obligation) to sell it to his junior? Even if the junior partner was not actually prevented by his agreement from exercising his option before the appointed day, there is no reason why the senior partner should be permitted to appropriate all right to compensation for it. If that is the force of the proposals (a) and (b) of our representatives, then the profession and in particular junior partners, may have good reason to hope that we shall be better represented in future—I am, etc.

Eye Suffolk

J SHACKLETON BAILEY

\* \* The Secretary of the Association writes. The effect of the recommendations where both or all the partners join the Service is that, at the appropriate time the partner who would have been the purchaser acquires a share without payment. The junior purchaser receives a free transfer the senior "vendor" receives compensation due on the share transferred.

### Capitation Fee

SIR,—The basic wrong still remains—namely, that the capitation fee is paid out of a pool and is subject to deductions. The only possible deduction is the 6% superannuation payment. Practitioners should be paid honestly an agreed and adequate fee from the Treasury. We are not interested in the manoeuvre of paying so much into a pool and then monkeying about with percentages and estimates by local executive councils. It is outrageous that £13 million should be subtracted to constitute a mileage fund. Peter is just being robbed to pay Paul. There is no sense or justice in claiming mileage if you know that your brother practitioners are so much the poorer. Mileage is an 'extra' not a deduction.

As regards the payment of basic salaries as distinct from capitation fee payments, why should one have a priority over the other? Both have got to be honoured equally and punctually. It is just not understandable why percentages and reserves have got to be set aside and guessed and under- or over-estimated. Pay the doctor what is due, not what is left over from an inadequate, arbitrary pool. Why on earth should a doctor in London be paid at 3s 9d and in Bristol at 4s 0½d? Both have entered the Service on the same terms and with the same heavy commitments, both may have that quarterly cheque as their sole income till Christmas—nothing coming in weekly or monthly—and yet the local executive committee have the power to withhold moneys at their whim and pleasure, and even do this to the extent of 9d per caput in London. The whole situation seems fantastic and barely believable. Luckily we have a generous and co-operative committee in our area.

Are the administrators of the NHS paid their salaries in similar fashion, fluctuating from time to time and place to place? I see discussions with the Ministry are now being sought and figures are being reviewed. Can we hope that the Ministry having got us safely in the bag, is likely to discuss anything?—I am, etc.,

Croydon Surrey

J W WAYTE

SIR,—I am stimulated to join in with the list of dissatisfied doctors who are writing letters to the B.M.J. by the excellent letter from Dr S. T. Pybus (*Supplement*, Oct 16 p. 143), who in my opinion expresses many of the thoughts which many of us have stored up in our minds. Doubtless much of our trouble has been brought upon ourselves by our insistence on the high ethical standard with which we approached the Service and the directions we gave to our negotiating body, combined with our childlike trust in the negotiators of both sides. Now, after receiving our first quarter's cheque, we are able to look upon the Service from a more practical angle—to realize that

we are going to find ourselves financially much embarrassed and that the position that we have struggled so hard to gain during the years we have been in practice has rapidly changed for the worse

Not only has this position changed financially, but also ethically, so that we are placed in such a position that we must accept so large a number of patients on our lists that it will be impossible to provide them with the amount of considered attention and skill to which they are entitled. Dr Pybus's suggestions of limitation of *capita* scaling of remuneration, and retrospective consideration of years of service under the NHI scheme to count for pension seem to me to be eminently practical and worthy of consideration. The present position, with surgeries lasting from two to three hours morning and evening a visiting list stretching anything from thirty to fifty or more daily with one so called half-day per week and a curtailed Sunday list seems to me to be a prostitution of the profession—I am, etc.,

Highcliffe-on-Sea Hants

E C PARKER WILLIAMS

SIR,—I should like to associate myself with the letter of Dr S T Pybus (*Supplement* Oct 16, p 143). There is no doubt in my mind that a doctor in the NHS should not be allowed to look after the health of more than 2 500 patients, as he or (she) cannot do justice to himself or the patients. Doctors with a list of 4 000 patients will find themselves—if it is a severe winter—with 10% of their list requiring visits when the weather is at its worst. To visit 400 people a day is an impossibility.

With regard to payment I consider that a capitation fee of £2 per head is fully justified if the doctor has the welfare of the patient at heart and treats an NHS patient as if he were treating a private patient.

Finally it would seem to be extraordinary that the BMA does not insist on the basic salary being paid automatically—without the degrading cross-examination at present required—to every general practitioner with a panel under 1 000. It is annoying to say the least of it, to hear of young dentists and opticians earning £200 a week while the young doctor, with a much greater responsibility, has to go cap in hand for £300 a year. I consider that it is the duty of the BMA to attend to the wishes of the members in these matters—I am, etc.,

Glasgow

CONSTANCE F ROSS

### Financial Strain on Young Specialists

SIR,—I read the letter from 'Ex-Service' (*Supplement* Oct 16 p 144) with a great deal of fellow-feeling. I hope that he might be interested in the position of one who did not serve and will agree with me that the whole question of remuneration for young specialists should be reviewed.

Turned down on medical grounds, I spent the war years in hospital positions and in an 18 months spell in general practice. My maximum salary in the latter was £650 after 12 months at £500 p.a. Prior to this I received £200 p.a. in hospital as a maximum. This is, on balance, less than a serving officer received in salary and allowances. I could save little and with the pressure of work could only study very late at night. I had one child at the time.

After the war I obtained my postgraduate qualification after 12 months study in London. I was not paid while studying and had to rely on parental help to maintain myself and family. Now I am a whole time specialist—rooms obviously being out of the question in such times. Though my salary is £1,250 per annum, tax and superannuation take a large slice out of this. In addition a whole time specialist cannot claim car expenses against income tax except for inter hospital travel, and the State does not allow such expenses the hospital being deemed HQ for this. I thus pay over £100 per annum to run my car—out of income. Let this be a warning to potential whole timers. In addition, I have had to buy a house, and this has again to be paid for. As I now have three children, my bank balance does not show a profit at current prices after 12 years as student and doctor.

The moral is to pay specialists during and after training a salary commensurate with their training and liabilities—professional and social. The vast majority of us are all similarly placed whether we were in the Forces or not, if in our early thirties. This perhaps explains the interest many colleagues show in permutations. A last word of warning to a future whole-timer. A part time specialist was paid a fee for doing

my holiday locum. I was due to undertake a similar locum which did not eventuate. When I made inquiries I was advised that a whole time man could not be paid any extra for such work. This is since July 5, his whole time salary covers all work—I am, etc.,

HOME FRONT

### Civil Service Medical Officers

SIR,—The letter from 'Civil Service MO' (*Supplement* Oct 9, p 134) raises a very important issue, as, although many of the Civil Service medical officers have staff representation through the Institution of Professional Civil Servants, which has done Trojan work on their behalf, the IPCS has always been limited in its efforts for medical officers because the official side (i.e., the representatives of the Treasury) has always refused to concede even parity in salary scales of the professional classes with the administrative classes, and medical officers' salaries are therefore kept at an unjustifiably low level merely because the medical officers' non professional bosses are not considered worth a relatively higher salary. There is also a danger that in BMA negotiations the Treasury can say, 'But we have already negotiated successfully salary scales for large numbers of well qualified doctors on figures which are much below what you ask.'

These large numbers of doctors have had to accept these salary scales willy nilly, and have done so patiently hoping that they would share in the final settlement made by the BMA. Unless the BMA takes active steps to ensure in the final settlement that established Civil Servant medical officers including those of consultant status—and I emphasize this, as many of us are of consultant status but are refused recognition of this and paid as basic grade of medical officer—have their salary and conditions of service brought into line with the rest of the profession a grave injustice will be perpetrated. Civil Servants are to a very large extent a "silent service" and cannot ventilate their grievances openly. What about it, BMA?

ANOTHER CIVIL SERVICE MO

### Earnings of Specialists

SIR,—This letter is addressed specifically to the medical men and women who intend to become specialists. The Spens Committee has recently proposed your future salaries. For the benefit of those of you who cannot take a few days vacation for the purpose of minute study of this report, I have outlined below a fairly complete but basically simple sketch of the income you will receive in the future. The average age of qualification including military service, is 25 years of age.

You commence with an A appointment and follow this with a B2, lasting six months each. The Spens Report offers nothing for this first year, it completely ignores it. You now procure a Grade III appointment, which you hold for one year. You are paid £600 for this year, but this is non resident pay. If you live in the hospital, which is usually compulsory, you pay £200 for your emoluments. Thus, you only earn £400. Your age is now 26 years.

The year goes by and more by influence than luck you obtain a Grade II post. You are now a junior registrar and hold the appointment for two years. You receive £700 for the first year and £800 for the second—minus, of course, your emoluments making your salary £500 and £600 respectively. You are now 29 years old. Perhaps you are unfortunate in having a wife and even doubly cursed if you have a child. 29 years of age and earning £600 per annum.

By now you should have a higher qualification. I should like to add here that in studying for higher degrees there comes a time when you have to stop clinical work and take to the books and perhaps attend courses. Otherwise, why are there so many courses available? While you take off your few months for this purpose you earn nothing, you even pay for these courses. It is again unfortunate if you or your family have appetites.

Now you scramble for the less numerous Grade I posts—first assistants. You are 30 and, if non resident, receive £900. For the next year you earn £1,000.

At present the policy of the powers that be is to discourage specialization—the need for more practitioners is great. As a GP you will not have to wait until you are 31 years of age before you earn the princely sum of £1 000 per annum. Remember too we still have to pay for our six years of medical training. Finally, the Government states that the cost of living has risen only 13% since 1939. Tell that to the shopkeepers and

## Shortage of Forces M O s ?

SIR,—I apologize for adding yet another M O s grouse to the many you have doubtless received in the past I am only constrained to write by the fact that I am one of those recently qualified men who were called up after only six months in a house appointment I was prevented from taking an invaluable B2 post with its opportunities for training for a higher qualification by an autocratic edict which referred to the imminent severe shortage of M O s in the Forces

At my present unit in England there are at present four M O s, approximately 1 600 men and women, and a small CRS of 12 beds at the moment containing four patients These figures speak for themselves For the benefit of the CO at the R A M C training depot I would say that I cannot occupy myself with unit hygiene and welfare matters as, being M O to the CRS that's outside my job

I am extremely fortunate in having a good civilian hospital handy which enables me to continue my studies for a higher degree in my present circumstances I am aware that the three months' extension of service may in part be responsible for this state of affairs—I am, etc,

CRS M O

## Salaries of Medical Officers of Health

SIR,—I am concerned about the position of medical officers of health throughout the country in regard to salaries It would appear to me in so far as I can judge from my own observations that the British Medical Association has done little or nothing to increase the salaries of medical officers of health whereas much has been done to increase the salaries of general practitioners and consultants It will be a tragedy if the present cloud which overhangs public health is not lifted So many of its best medical officers of health have left for the service of regional hospital boards, and young male doctors seem to be choosing other branches of medical service as their life work The great work which preventive medicine has done and has still to do for the health and welfare of the people of this country must not be forgotten and I appeal to the British Medical Association to endeavour to bring the salary scales of medical officers of health to a level in keeping with those of other members of the profession—I am, etc

Bailey Yorks

W J FRAIN

\* \* The Secretary of the Association writes Apart from negotiating interim increases of 25–35% in the pre-war Askwith Scales the Association has submitted to the Ministry proposals for permanent revision of the remuneration of the public health service

## POINTS FROM LETTERS

## Recruitment of Young Practitioners

Dr J D BURY (London E 1) writes It was very pleasing to see by "Surgeon Lieutenant's letter (*Supplement*, Aug 28, p 96) that someone else has noticed the shameful decision regarding the appointment—or rather the non appointment—of newly qualified practitioners to 'B' posts I do not think it is generally realized to what extent the group involved has already suffered the 'slings and arrows of outrageous fortune' While it is fully understood that they have not had to bear the set-backs of their seniors who have experienced upwards of three years in the Forces, I would like to point out some of the many circumstances which have already led to their education being interrupted and incoordinated Preclinical studies were undertaken in many instances in foster homes in the provinces where quarters were cramped and laboratory facilities overburdened The course was further interrupted by re-evacuation back to the parent school Here preclinical and early clinical studies were undertaken through blitzes—ordinary and of the buzz bomb and rocket variety (I well remember candidates and examiners ducking under tables when I took 2nd MB) Some started their clerkship and dresserships in sector hospitals which were in the process of closing down Introductory courses were

perfunctory or non-existent, due to shortage of teaching staff Other subsequent improvements, such as the tutorial system were denied for the same reason Midwifery experience was limited, due to the withdrawal of teaching units from municipal hospitals before the teaching hospitals districts had regained their pre-war size This meant that many students were hard put to it to achieve even their statutory fifteen cases The years immediately before us had had the advantage of increased practical experience in the sector hospitals Student house officers had then been plentiful The years immediately after us have had fully co-ordinated clinical teaching, and in some respects increased clinical experience Yet now it is precisely on our group, and on our group only, that the axe again falls Clinical experience as house officers was what we had been pinning our faith on, and this has been taken from us due to the needs of the Forces," as the Minister says This when on all sides we hear examples as gross as nature of the wastage of medical man-power in the Forces We have no desire to shirk our responsibilities to our country and many are looking forward to a period in the Forces however, it seems to have been forgotten that part of our responsibility to our country is to be good doctors, and we will not be such efficient practitioners if vital clinical experience is denied us

\* \* A statement on the recruitment of young practitioners was printed in the *Supplement* of Oct 16 (p 144)—ED, B M J

## Mould the Service

Dr J F ROBINSON (Garforth, Yorks) writes It is several months since we told the B M A to go ahead and do the best for us in the new Service But what has it really done to help its members and what is it now doing? What, indeed compared with the B D A? It is high time the responsible committee—if one there be—did something to prove its worth Six months ago we were advised to accept the Minister's final terms in order to give the leaders of the B M A time to mould the new Service so that it would be a pleasure and an honour to work in it and a service really worth having Those leaders do not appear to have helped the profession very much in the moulding process and I suggest they recast it in the shape of a mint

## Prescribing and Dispensing

Dr A HENRY GREGSON (Cromer, Norfolk) writes I regret most sincerely that you should make a laughing stock of any Minister of our Crown yet in Section 14 of the Report of the Insurance Act Committee for 1948 (*Supplement* Oct 16 p 135) your report that he thinks prescribing and dispensing are inseparable makes him so For now every doctor, consultant included, must dispense (drugs as well as wisdom) After all, if your report is correct he cannot have it both ways

## Capitation Fee

Dr BARBARA J HICK (Lee on the Solent Hants) writes I hope the General Medical Services Committee will make it quite clear to the Minister that a capitation fee of 17s 5d is not a living wage We were given to understand before we joined the Service that the capitation fee would be 18s 6d Now the highest figure mentioned is 18s and mileage, etc, deducted from that A minimum of 18s 6d with the present allowances added will barely be enough to cover overhead expenses, but applications for further allowances are turned down Unless we can have locums and reasonable holidays as well as the concessions already refused we must have a higher capitation fee, or each one of us will be faced with bankruptcy The position is serious enough to warrant universal resignation unless pay is materially improved

Dr C E BROWN (Whalley, Lancs) writes With the present extremely high cost of living the capitation fee should be not less than 45s per head per annum It is a most vital point which must be ever pressed that a living wage is absolutely essential The young principal building up a practice has many commitments far greater in these present times than were considered by the Spens Committee Values have changed beyond conjecture and must be appreciated now This brings me to the question of the basic salary This question is at present being considered by the local executive councils It surely must be appreciated that any fixed sum of money considered, as an aid to the young principal building up his practice must be a complete sum and must not be quartered To split such a sum into quarterly payments of £75 will defeat the end for which it was intended May I conclude with a repetition of my earnest recommendation that we should all demand a living wage?

## Prescribing by Retired Doctors

Dr N J C RUTHERFORD (Farnham Surrey) writes I am glad to see that retired doctors have raised the question of being deprived of obtaining medicines on their own prescription free of charge I have always saved local practitioners trouble by prescribing for myself family and employees in all minor ailments Surely prescription pads under the NHS could be issued to retired doctors?

## H M. Forces Appointments

### TERRITORIAL ARMY

#### ROYAL ARMY MEDICAL CORPS

Colonel G J V Crosby, CBE, TD, has been restored to establishment from Supernumerary List (The notification in a *Supplement to the London Gazette* dated Aug 6, and in the *Supplement to the Journal* dated Aug 21 (p 92), is cancelled)

Lieutenant Colonel G B Mitchell Heggs, OBE, has been granted the acting rank of Colonel

Major (War Substantive Lieutenant-Colonel) J P Raban, TD has been granted the acting rank of Lieutenant-Colonel

Majors G A Kane, OBE, TD, and T D Pratt have been granted the acting rank of Lieutenant Colonel

Captain (Acting Lieutenant-Colonel) J H Prawn to be Major

Captain (War Substantive Lieutenant-Colonel) M L Formby TD, to be Major

Captain J A Perpoli to be acting Lieutenant-Colonel

Captains (War Substantive Majors) W B Evans, H Dickie, C N Suter and C H Imrie to be Majors

Captains J B Mackay, MBE, J G Oliver A V Russell, and B St J Steadman to be Majors

Captains A Barber MC W J Aitken, and C K Sconce to be Majors, and have been granted the acting rank of Lieutenant Colonel

Captains T F Redman and K H S Dalwall to be acting Majors

Lieutenant L H V Longmore to be Captain and has been granted the acting rank of Major

Lieutenant (War Substantive Captain) J A R Johnson to be Captain

Lieutenants B Andrews C Nicholson, MC, M I Hepburn, R M Harvey, R Lamb, C K Bridge W A M Smith B H M Cohn, W A Bromley, C E C Wells, R M Marsden, and R Creece to be Captains

R V Stone to be Lieutenant and has been granted the acting rank of Major

The notification regarding Lieutenant R M Marsden in a *Supplement to the London Gazette* dated Sept 14 has been cancelled

#### TERRITORIAL ARMY RESERVE OF OFFICERS ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel J W Craven, MC, TD, having exceeded the age limit, has relinquished his commission retaining the rank of Lieutenant-Colonel (Substituted for the notification in a *Supplement to the London Gazette* dated Dec 2 1947)

Major (Acting Lieutenant Colonel) R A S Keighley, from Active List, to be Major, and has been granted the honorary rank of Lieutenant-Colonel

Major W J Aitken, from Active List to be Major, and has been granted the honorary rank of Lieutenant Colonel

Majors J M Dewar and C V Light, from Active List, to be Majors

Captain (Acting Major) G T Ashley, from Active List to be Captain and has been granted the honorary rank of Major

Captain G Punshon has relinquished his commission on account of disability and has been granted the honorary rank of Major

Captain F H Leckie, from Active List, to be Captain

## Association Notices

### FORMATION OF CAITHNESS AND SUTHERLAND DIVISIONS

Notice is hereby given by the Council to all concerned of the formation of a Caithness Division comprising the area of the County of Caithness, and a Sutherland Division comprising the area of the County of Sutherland, in place of the existing Caithness and Sutherland Division

CHARLES HILL  
Secretary

### Branch and Division Meetings to be Held

SOUTH ESSEX DIVISION—At Dagenham Civic Centre Fri 5 Nov 5 9 pm Dr A E Clark-Kennedy 'Indigestion'

### Meetings of Branches and Divisions

#### ALDERSHOT AND BASINGSTOKE DIVISION

At a general meeting of this Division held on Oct 24 th no resolution was passed unanimously

"That this meeting regards with grave dissatisfaction the results of negotiations to date and requests the Association to inform the profession what measures it is taking to secure the implementation of the Spens Committee's recommendations and what steps it is prepared to recommend to enforce such implementation"

## THE ROLE OF SPECIAL DIETS IN THE TREATMENT OF FEMALE INFECUNDITY

BY

MARY BARTON, MB, BS

AND

B P WIESNER, D Sc., Ph D

First Assistant Fertility Clinic Royal Free Hospital

Consulting Biologist Royal Northern Hospital

Infecundity in seemingly healthy women is often associated with infective conditions whose eradication may bring about, or assist in, the restoration of fecundity (Lane Roberts *et al*, 1948). However, refractory cases of infecundity combined with infective states are common. In these the infection cannot be eliminated either by antibiotics or by other and more drastic procedures, nor do they respond to the more specific methods for the treatment of infecundity. We have noted that this refractory state is particularly common in women aged 30 to 40 who are either distinctly overweight or frankly obese. The combination of overweight with refractory infecundity of this type could not be regarded as fortuitous, for, quite apart from our own observations, previous authors have emphasized the close association between obesity and sterility (Aschner, 1924, Baucr, 1934, McCann, 1934, Siegler, 1944, Guggisberg, 1946) and have advised the use of various reducing diets involving lowered energy intake.

In view of the generally accepted relation between nutritional state and reproductive function we also instituted dietary measures. In our cases, however, the strict rationing involved in the prevailing food situation, and the bacteriological findings, suggested a qualitative change of diet rather than lowered calorie intake only. These dietary measures assisted in the restoration of fecundity in a number of previously refractory cases, and are described below. The present report will be limited, however, to one section of these cases—namely, women in whom the major sterility factor discovered on investigation was cervical dysfunction associated with cervical infection and resulting in non-receptivity to spermatozoa ("cervical block"). This limitation commended itself to us for several reasons. First, cervical block probably represents the most common immediate "cause" of sterility (Palmer and Palmer, 1945) in women aged 30 and over; secondly, the present investigations were suggested by findings in such cases, namely the general condition of the cervix and its functional state are readily ascertained by precise laboratory and clinical methods (Lamar *et al* 1940, Barton and Wiesner, 1945, Clift, 1945, Viergiver and Pommerenke, 1946) so that corrective measures can be readily assessed. Lastly, the state of the cervix, though only one of the factors in genital function, often reflects the state of the reproductive system as a whole. Thus facts relating to cervical responses have a wide validity.

### Subjects

The investigations were carried out during 1946-8 and concerned 88 women aged 30 to 40 with a history of primary or secondary sterility, in the latter group are included women who had conceived but aborted. All subjects sought advice because they desired children and not for any clinical complaint. They were women of widely different social status, and included many housewives with arduous

duties and some women with outside employment in addition. A few were doing work requiring considerable output of energy (e.g., market gardening).

Minor complaints or deficiencies were common in this series, particularly constipation, mild and transitory rheumatism, dental sepsis, nasopharyngeal catarrh, and sub-clinical infections of the urinary tract. Nearly all the patients complained of high fatigability and abdominal distension after meals. We have excluded from the present series any case with marked departure from the menstrual norm or with other than diphasic temperature records, or with any severe chronic illness.

### Cervical Condition

In all cases the *initial cervical examination* was made during the late follicular phase—that is to say, during the days immediately preceding, and including, the shift of the waking temperature from the low to the high level. At this stage of the cycle the mucus secreted by the fecund woman is abundant and clear, while in the subfecund woman deficiencies of secretion are least pronounced, probably because of the temporary increase in cervical flow at this time. Conditions for invasion by spermatozoa are thus optimal, and failure of invasion at this stage may consequently be regarded as a reliable and definite sign of cervical dysfunction. In many of the cases the volume of the mucous cascade was abnormally reduced, and erosions, small occlusion cysts, or other clinical signs of cervical infection were present. In other cases the macroscopic appearance of the cervix was not demonstrably abnormal. The rheological properties of the cervical mucus, such as fibrosity (capacity to form threads), varied from the normal to the definitely abnormal without any constant relation to the appearance of the cervix. An invasion test was carried out in every case, the cervical mucus being brought into contact with fecund semen under anaerobic conditions according to the standard method (Barton and Wiesner, 1946). As mentioned before, the present group includes only cases of severe impairment of cervical receptivity (complete absence of sperm invasion or sparse and shallow invasion with rapid inactivation of sperms). In about 70% of the cases the number of exfoliated epithelial cells and of polymorphs, which are scarce in normal ovulatory mucus, was increased, often to a density resembling that normally prevailing in the luteal phase.

The *second cervical examination* was carried out as close as possible to the onset of the next menstruation (late luteal phase). This stage was chosen because our experience has shown that infective and inflammatory processes in the cervix are exacerbated at that stage of the cycle. Pathological processes which may be masked during the follicular phase can thus be recognized, and the identification of pathogens is facilitated. The latter task is of significance in

the treatment of cervical block. It is true that in some such cases no organisms have been demonstrated which could be regarded as pathogenic by any standard. Conversely, not all infections of the cervix produce cervical block. But in the great majority of cases either undoubted pathogens (e.g., coagulase-positive chromogenic staphylococci, *B. proteus*) or organisms suspected of being pathogenic in this site (e.g., coliforms) can be recovered, their nature and their *in vitro* responses determine the choice of antibiotics. Furthermore, culture of the cervical mucus is essential in order to distinguish between infective and non-infective cervical block—a distinction which cannot be made by any other means.

During the pre-menstrual examination the cervix was exposed with the appropriate precautions against contamination (cf Kuester, 1929, Hite *et al.*, 1947) and a loopful of cervical mucus, obtained after thorough dry swabbing from just within the external os, was planted out on warmed blood-agar slopes. Additional inocula on other media were made as required. The inocula were submitted without delay to the laboratory. In view of the great variety of organisms that may infect the cervix detailed bacteriological examination was carried out\*.

The present series includes only cases in which pathogens or suspected pathogens were recovered, but excludes cases of Neisserian infection. The findings are illustrated by the results in 25 successive cases (Table I). This table

TABLE I—Showing the Presumptive Pathogens Recovered from the Cervix in 25 Successive Cases of the Series. Reference to Presumptive Non-pathogens Commonly Recovered (e.g. *Staph. albus* diphtheroids) is omitted

does not include the full variety of organisms recovered on culture, but it shows the predominance of infection by coliform organisms. In view of the precautions taken against contamination and of the heavy growth usually obtained, the cultures probably reflect the true flora.

\*The bacteriological routine procedure employed anaerobic culture for 48 hours followed by aerobic conditions for, usually, 18 hours at 37°C. At this stage it was decided, from the colonial characteristics and the Gram films of the primary culture, what further information was necessary to arrive at the true state of the cervical flora, and subcultures of colonies requiring identification were made on the appropriate media. MacConkey's medium and SS (as an enrichment medium) were generally used to identify genuine non-lactose-fermenters and were followed by the carbohydrates for two or three days for final confirmation. Nutrient agar was used for growing suspected genuine chromogenes such as *Staph. aureus* for the coagulase test, and *Ps. pyocyanea* is also easily identified by this means. Sensitivity tests with antibiotics were carried out in the appropriate subcultures.

though not necessarily the whole flora, of the blocked cervix in these cases. It is of course impossible to ensure that a loop will not in any circumstances take up organisms from the border between cervical and vaginal epithelium. The term "cervical flora" is thus subject to qualification imposed by the technique. But while in some cases the vaginal films and vaginal inocula showed an atypical vaginal flora, the pathogens cultured from the cervix were not generally also found in the vagina, and vice versa. Thus coliform organisms are sometimes recovered from the cervix and even the urine, but not from the vaginal wall proper. It must also be added that an abnormal cervical flora may vary from cycle to cycle even to the extent of one pathogen being replaced by another without manifest cause.

### Response to Antibiotics and Oestrogens

Impaired cervical receptivity that is combined with infection often responds to the administration of oestrogens which stimulate cervical secretion and condition its receptivity for spermatozoa, provided that infection is first dealt with by suitable treatment—e.g., sulphonamides, penicillin, or other antibiotics used locally or systemically or both. The response is usually manifested not only in the favourable results of the invasion or post coital tests, but also in the macroscopic appearance of the cervical flow. This becomes abundant and transparent, with reduced diapedesis of leucocytes.

The present cases were characterized by the absence of this response or by a partial response only. Notwithstanding the administration of antibiotics and oestrone (1.5 to 3 mg in microcrystalline suspension per week for four to twelve successive weeks) the mucous flow remained scanty, or else it increased without becoming receptive for sperms. Again, pathogens could be recovered at any time during or after the treatment with antibiotics. Some of these cases had previously received local treatment for cervicitis, including cautery, with varying response of the local lesion but with persistence of cervical block.

### Body Weight

As stated above, the present group is composed entirely of cases showing distinct overweight—i.e., more than 10% above the mean weight for age and height. The degree of adiposity varied widely (see Graph). In the pronounced

Graph showing changes in body weight under treatment (The asterisk denotes date of commencement of diet).

— Woman aged 32, height, 5 ft 2 in (157.5 cm) *B. coli* infection of cervix. Lactose diet (Group I)  
 --- Woman aged 31, height, 5 ft 3 in (160 cm) *B. coli* infection of cervix combined with vaginitis (mixed infection including *Trichomonas*). Simple sugar-free diet (Group II)  
 ---- Woman aged 32, height, 5 ft 3 in (160 cm) *B. proteus* infection of cervix. Supplemented by sugar free diet (Group III)

cases adiposity—if the term may be used without prejudging the nature of the deposits—was most marked in the subscapular region, the waist, and the thighs. In the frankly obese women no specific distribution could be noted.

### Therapeutic Methods and Results

In refractory cases it was at first intended to employ recognized and well-tried reducing diets involving severe restriction of calorie intake or to adjust the salt balance but most patients were working too hard to be easily placed

on a severe reducing diet, nor could they spare the time for treatment in hospital. Most of them could not afford to purchase much unrationed protein, and it certainly did not seem safe to lower fat consumption below that provided by the rations. A different approach, suggested by the predominance of infections by organisms of intestinal type, was therefore chosen—namely, an attempt to reorganize the intestinal flora. This form of therapy has been widely advocated by previous workers for many different conditions, including genital infection. Three specific procedures were used in successive groups of patients.

#### Group I (Lactose Group)

The first method chosen (14 cases) was the administration of lactose (Lactose B P, 3 oz (85 g) daily), for numerous investigators have agreed that this sugar, administered in comparatively small quantities, assists in the establishment of a favourable intestinal flora (for bibliography, see Robinson and Duncan, 1931, Robinson and Gilliland, 1937, Koehler and Allen, 1934, Koehler, Rapp, and Hill, 1935, Webb and Whittier, 1948, Rojas *et al* 1948), and has only mild side-effects, such as slight laxative and diuretic action (Hunt, 1931, Koehler, Rapp, and Hill, 1935). With the intention of enhancing the reputed action of lactose, ordinary sugar (sucrose), as the most ready source of fermentable carbohydrate, was eliminated from the diet. An additional reason for the experimental elimination of sugar and its replacement by lactose was supplied by the results of experiments in rats carried out by Whittier *et al* in 1935. They placed paired groups of rats on diets containing lactose and sucrose respectively and found that the lactose diet prolonged the span of life compared with the sucrose diet. Furthermore, the sucrose-fed animals developed significantly larger deposits of fat than those receiving lactose. It seemed possible that not only was lactose beneficial—as claimed by various observers—but also that sucrose was actively deleterious by promoting abnormal adiposity.

All our subjects, therefore, were instructed to avoid rigidly any article of food or drink containing sugar (biscuits, cake puddings, sweets, etc), and not to add sugar to food or drinks. Glucose and syrup were not allowed either. No restrictions were placed upon other foods, whether rich in carbohydrates or not, and the subjects were told to still hunger by eating more of permitted foods (e.g., bread, potatoes, etc) than they did before being placed on the diet. The only medicament advised was mucilage where necessary to promote bowel action.

All subjects found the diet difficult to observe during the first few days and meals unsatisfying, but no ill effects upon working capacity were reported. Abdominal distension generally disappeared and subjective energy increased. Marked losses in weight occurred in all but three women of this group, the loss becoming apparent within one week of beginning the regime. The average loss was about 1 lb (450 g) per week, and the rate of loss was not clearly related to the initial weight. Weight continued to fall until a level approximately corresponding to the mean weight for age and height was attained. In some cases the weight remained stationary rather above this level in spite of the continuation of the diet.

The lactose diet was continued for at least four weeks before further steps were taken, re-examination being carried out in the second cycle after starting the regime and being repeated as required. In three cases spontaneous recovery of the cervix, with positive invasion tests, was then noted, but the dietary regime alone did not, as a rule, entirely restore cervical function even when body weight was much reduced.

Where invasion continued to be impaired (i.e., in all but three cases) treatment with antibiotics and oestrone was now resumed, the diet being continued and the procedure being in all essentials a repetition of that previously used without success. It was then that entirely different responses were recorded in a further six women, all of whom had shown loss of weight. The mucus assumed normal volume, transparency and invadability in these cases; epithelial lesions healed without further intervention and without relapse in subsequent cycles. Conception occurred in four women, but male fecundity varied so much in this series that the conception rate does not reflect

the response as adequately as does the occurrence of a positive invasion test. Cervical recovery failed to occur in five cases, three of which had shown no significant reduction of weight.

#### Group II (Sugar-free Diet Without Lactose)

The second method chosen (65 cases) differed from the first solely in the omission of lactose, the subjects were simply placed on a "sugar-free" diet. All other instructions and procedures were precisely the same as in Group I. This regime was originally chosen to ascertain whether administration of lactose was an essential factor in the treatment of refractory cervical block.

The results showed unequivocally that lactose was not necessary for the desired results, and the group was then expanded. The sequence and rate of responses (reduction of weight, restoration of cervical function under repeat treatment with antibiotics and oestrone) resembled that in Group I so closely that no detailed description is needed. Cervical block was removed in 45 cases, conception occurred in 24, but, as in all such series, the conception rate is not an adequate measure of female fecundity, and the series includes cases in which treatment was but recently concluded. Incidental subjective responses (relief from post-prandial distension, decreased fatigability) occurred in this group as in the first, and in several cases infections of the urinary tract disappeared together with the cervical block. In this series there were several cases in which distinct cervical improvement took place under dietary regime alone. There were two cases in which no loss of weight occurred but the cervix responded to repeat treatment. In other responsive cases loss of weight had taken place. There were 18 failures (see Table II).

TABLE II

Dietary Group	No of Cases	Cases Showing Loss of Weight		Cases Showing No Loss of Weight	
		With Cervical Response	Without Cervical Response	With Cervical Response	Without Cervical Response
I Lactose group (sucrose free)	14	9	2	—	3
II Sucrose free group (without lactose)	65	45	12	2	6
III Supplemented sucrose free group	9	6	—	—	3

#### Group III (Supplemented Sugar free Diet)

In the present circumstances sugared foods supply a large proportion of the total energy intake of our subjects. Conversely their elimination from the diet involves a severe reduction in energy intake unless it is balanced by increased consumption of unsugared foods. Most of the subjects in Groups I and II clearly compensated themselves by such adjustments. Hence it seemed that reduction in weight and restoration of fecundity could occur without significant reduction of energy intake. But it seemed desirable to test this conclusion by specifically prescribing to a number of subjects a sugar-free diet which did not involve for any case a decreased calorie intake and for most cases in fact procured a significant increase.

The composition of the diet in this group (9 cases) was dictated, first, by our intention to provide a diet which in certain experimental animals, and so far as is known in man, is adequate for maintenance and for reproduction (whole grain, milk), secondly, by the limited variety and quantity of foods available to patients with small incomes, thirdly, by the need to avoid additional work—i.e., in procuring or preparing food.

The diet prescribed excluded (1) all foods containing sugar, as in Groups I and II, (2) breakfast cereals and other foods prepared by toasting. It included explicitly all rationed foods except sugar, bread (85% extraction), oatmeal, unrationed vegetable oil, fruit, fish, potatoes, and yoghurt, which is unrationed and available to anyone living in London. The subjects were instructed concerning the purpose of the regime. Although with few exceptions, they were not asked to weigh their food or to adhere to specific menus, they were clearly told the approximate minimal quantities which they were to consume per day.

The general and the cervical responses resembled those seen in Groups I and II. Loss of weight occurred at about the same rate as in those two groups. In three patients the weight

remained almost constant. Cervical function was restored in six who had lost weight, and conceptions have occurred so far in two. This group, like Group II, contains a number of recent cases, so that the incidence of conception cannot yet be assessed.

As stated, the energy intake of several women of Group III was higher during the regime than before. Increased intake, in spite of the exclusion of sugar, was facilitated by the peculiar food habits not uncommon in obese women. Before treatment they ate no potatoes, hardly any bread and very little fat—all foods which they believed to be fattening. Being childless, they did, however, consume their own (and sometimes their husband's) sweet rations, and quantities of cakes, biscuits, stewed fruits, etc. Furthermore, they did not bother to prepare meals for themselves when their husbands were out, so that their "elevenses" lunches, and teas consisted quite often of a cup of tea or coffee with a slice of cake. When they were taken off sugared foods and ordered to eat bread, oil in addition to their fat ration, oatmeal porridge, yoghurt, and so on, they more than made up for energy intake surrendered with sugared foods. The subjects were not in hospital, so precise figures concerning calorie intake cannot be submitted, but in Table III gain and

TABLE III—Showing Loss of Energy Intake through Exclusion of Sugared Foods by a Subject of Group III together with Energy Intake from Additional Foods Prescribed to Balance this Loss\*

A Loss per Week through Exclusion of Sugared Foods	
Sugar (8 oz. 227 g)	860 cal †
Cake (purchased) (28 oz. 794 g)	2 800
Biscuits (16 oz. 454 g)	2 176
Jam (8 oz. 227 g)	560
Sweets (3 oz. 85 g)	450
Flour used in puddings (about 7 oz. 200 g)	680
Total	7 526 cal
B Gain per Week from Prescribed Minimum Intake of Specified Foods	
Oatmeal (14 oz. 397 g) taken as porridge and girdle cakes	1 400 cal
Yoghurt (14 bottles estimated at about 100 cal each)	1 400
Additional bread (28 oz. 794 g)	1 960
Potatoes (3 lb. 1 36 kg)	2 700
Vegetable oil (20 fl. oz. 568 ml) taken in salads and for cooking	5 100
Total	12 560 cal
Positive balance per week 5 034 cal	

\* The figures do not take into consideration meat, fish, cheese and other foods which were not significantly affected by the regime, nor do they reflect increased consumption of fruit and vegetables. The figures relate to the average consumption during a period of three weeks at the beginning of the regime. The subject, aged 32 years, height 5 ft 3 in (160 cm), weight 157 lb (71.2 kg), lost 6½ lb (2.7 kg) during this period.

† Calorie values obtained from Nutritive Values of Wartime Foods. Med. Res. Coun. War Mem. No. 14, London, 1945.

loss of energy intake are shown relating to a particular subject. From this it will be seen that in this clinical condition and in the prevailing food situation an increased calorie intake is compatible with a significant decrease in weight and an increased chance of recovery from cervical block.

### Supplementary Notes and Discussion

1 *Control Data*—Two groups of control data for the present series are available. First, the cases were unsuccessfully treated by oestrone, antibiotics, and sometimes local applications before institution of the diet. Experience shows that mere repetition of such treatment after an interval, and without intervening measures, rarely brings about success if it has failed the first time. The cases thus constitute their own controls. Secondly, properly organized therapeutic measures could not be instituted, or were interrupted for incidental reasons, in 9 patients. When these were seen again after intervals varying from two to six months restoration of cervical function was noted in but one case. Rapid spontaneous recovery without change in environment thus being rare, the regime appears to have contributed materially to the restoration of cervical function.

2 *Alterative Effect of Diet*—Previous workers found that infecundity in overweight women responds well to reduction of weight by decreased energy intake, by treatment for fluid retention, or by both. In our cases, too, the effect seems to be related to loss of weight. However, we

avoided any attempt to procure a negative energy balance. In some patients energy intake was possibly decreased simply by withholding sugared foods, in others, however, intake was not sensibly reduced, or was even raised. No did the patients produce a negative energy balance by increased exercise. In fact, in some of them the amount of work was deliberately reduced, for we are under the impression that such reduction, by imposed periods of rest, promotes recovery in women of this age group who have been exposed to continuous or excessive physical strain. It may thus be deduced that in such cases loss of body weight was due to a change in metabolism.

3 *Metabolic State and Infective Process*—This alterative effect may be responsible for the subsequent response to treatment. It is uncertain whether the response was related to an increase in general resistance or to a more specific action, or both, certainly general improvement in health occurred in many instances during the dietary regime. Resistance to infection is of course known to depend on nutritional conditions (Cannon, 1942; White, quoted by Duncan, 1947), and is lowered by specific metabolic disturbances (e.g., diabetes mellitus). But while alteration in the rate or the nature of metabolism appears to have favourably affected the infective process the connexion between infection and metabolic state in these cases cannot be regarded as a one-way relationship. Thus we have noted that the resumed treatment of the infection while maintaining the diet often accelerates reduction of body weight. Furthermore, the case histories show that increase in weight, and even rapid development of obesity, often dated from or followed upon, the first signs of genital infection or the infection of the urinary tract which not infrequently precedes cervicitis. The data are compatible with the suggestion that metabolic disturbances resulting in overweight and infective conditions of the type described are subject to mutual enhancement whatever the mode of origin may be.

4 *Metabolic State and Response to Oestrogens*—The restoration of cervical response to oestrogens may not represent an independent effect of metabolic changes but merely reflect the elimination of the infection. This interpretation suggests itself not only in view of previous findings already referred to but also because of other observations (unpublished). These show that in infecund women the reactivity to sex hormones (measured, for example, by uterine response to oestrogens and by endometrial or thermal response to progesterone) may be impaired by unspecific infections even if these are not localized in the reproductive system. Also pyometra, which commonly develops in aged rats, is often associated with suppression of vaginal response to oestrogens, the response may be restored by hysterectomy. It should be recalled, too, that the response to another hormone—namely, insulin—may be impaired by infective conditions.

5 *Role of Sugared Foods*—The only common factor in the three diets we employed was the exclusion of sucrose (with the exception of that occurring naturally in fresh fruit), and we are inclined to regard this as the essential factor. It seems likely that the high intake of sugared foods adversely affected metabolism either directly or indirectly (e.g., through promoting an unbalanced intestinal flora). The suspected effect of sugar may of course be conditioned by the form in which it is taken and which determines its availability for intestinal agents, and may be related to the diet as a whole (e.g., to the protein-carbohydrate ratio).

6 *Effect of Crude Sugar*—It seemed also possible that the adverse effect of sugared foods depended upon the use of highly processed sucrose, but the lactose used was also highly processed, yet it appeared to be harmless. Furthermore, 12 women were placed on a diet corresponding to that of Group II but received about 12 oz (340 g) of crude cane sugar per week. This diet did not evoke any loss of

weight or other response. Sugared foods were then entirely excluded from the diet, and the usual response occurred in these cases. The data, so far, certainly do not suggest that highly processed sugar is any better than the crude substance.

7 *Age Factor*—The relationship between refractory infertile conditions, metabolic state, and response to oestrogens is further complicated by an age factor, the threefold disturbance being comparatively less common in infertile women under 30. Its incidence seems to rise, like that of obesity in general, during the fourth decade of life. The complex here discussed represents one of the modes by which fecundity declines.

8 *General Notes*—The use of sugar-free diets is not suggested for cases of obesity in general, for our experience is entirely limited to infertile women in the reproductive phase of life. Also, the syndrome involving refractory genital infection, overweight, and lack of response to hormones may be determined by specific and topical conditions such as the prevailing food restrictions combined with the demand made upon the physical resources of women in this country during the past years. Nevertheless, we are submitting our findings because the dietary measures described have been of great practical assistance to us in our work, and in recent months dietary measures have been employed in every suitable case from the very beginning of treatment in order to save time.

#### Summary

Refractory cervical block is a common cause of infertile women aged 30 to 40. It tends to respond to treatment by antibiotics and oestrogens if loss of weight is first procured by dietary measures. Suitable diets which do not interfere with the routine of the subjects are described. Their main characteristic is the exclusion of sucrose with concomitant increase in other foods chosen to produce a diet adequate for maintenance and reproduction within the limitations imposed by rationing.

The bacteriological investigations for the present series were carried out by Dr R C Matson, pathologist, Royal Surrey County Hospital, Guildford, to whom our thanks are due for help and advice on many occasions. His routine procedure is summarized in the footnote. We are also indebted to Mr A L Bacharach for discussion of nutritional aspects of this investigation, and to the Scientific Adviser, Ministry of Food, for supplying crude cane sugar for issue to subjects.

## THE BIOLOGICAL ASPECT IN TREATMENT OF THE INFERTILE MARRIAGE

BY

R CHRISTIE BROWN, MS, FRCS, FRCOG

Honorary Surgeon, Samaritan Hospital for Women, Obstetric  
Surgeon, City of London Maternity Hospital

At the present day, when so many women seek advice with reference to the infertility of their marriages and so much investigation is carried out in an attempt to elucidate the causes, the criticism might be offered that most of our energies are spent in investigation and little in treatment. Nevertheless, many of our lines of investigation seem to have a direct curative value—as, for example, it would appear to be established that the performance of a tubal patency test has a curative as well as a diagnostic value. Green-Armytage (1943) has recorded a 43% success rate following the simple process of salpingography. It is not clear how this process achieves these results, but speculation upon figures quoted suggests that there is a direct relationship between the two. So many cases of immediate pregnancy following upon the simple procedure of endometrial biopsy have been reported that it is impossible to avoid the conclusion that here also the results are not merely accidental.

Reviewing treatment from the time-honoured method of dilatation of the cervix and curettage to the present-day methods of demonstrating tubal patency (salpingography and insufflation) and the surgical procedures of salpingostomy, it is at once apparent that most of our means of approach are mechanical. This is what might be expected in the present mechanical age and from the fact that the problem of the infertile marriage occupies the minds of surgeons rather than physicians.

Now that the role of the hormones of human gestation is becoming clearer and the endocrinologists are turning their attention to the problem, it is likely that the pendulum will swing a little away from the mechanical aspect towards the medical and biological side.

#### Four Important Questions

In investigating an infertile marriage we are concerned with four major questions: (1) The husband, his potency and the quality of his semen; (2) Ovulation; (3) The pathway which the sperms traverse to reach the ovum, and here we may consider two subdivisions—(a) the cervix and the influence of its secretions on sperm migration; (b) the Fallopian tubes; (4) Nidation or embedding of the ovum. In my opinion, the importance of nidation of the ovum has not been sufficiently stressed, and treatment based upon the assumption that many cases of infertility result from difficulty experienced by the ovum in embedding itself in the endometrium has proved to be successful in an appreciable number of my cases.

Since treatment based on the assumption of faulty nidation is purely medical and can be carried out with little inconvenience to the patient, it has gradually become my practice of recent years to initiate medical treatment aimed at securing firm implantation of the ovum in practically every patient who consults me with reference to infertility and in whom there is no gross pathology. Medical treatment can be undertaken while the patient is awaiting the propitious moment for such tests as the post-coital test, endometrial biopsy, and the tubal patency test and while the husband is being investigated by a seminologist.

Under such treatment it is surprising how often the completion of these tests is not necessary because the patient has become pregnant in the interim. Occasionally, of course, at the first examination one finds some definite and likely cause for infertility which calls for specific treatment, but more frequently no gross cause is discovered. In these latter cases treatment aimed at securing firm nidation can be started at once. In most of the patients nowadays, apart from performing a post-coital test, I like to give a trial period of two or three months under medical treatment before further investigations are undertaken.

Most authorities agree that the ovum, after fertilization, takes several days to traverse the Fallopian tubes and reach the uterus, the endometrium of which should be prepared to receive it—that is, it should be in the secretory phase, having responded to the hormones elaborated by the corpus luteum. An extended experience of endometrial biopsies taken just before the onset of a period has led me, however, to appreciate that all endometria do not show the same degree of preparation. Whether this is due to a deficient action of the corpus luteum or, as Bourne (1947) suggests, to lack of a receptive factor in the endometrium rendering it unresponsive to a normal hormonal stimulus must await further work on the subject. The fact remains that a good number of women produce an endometrium which, by our gross methods of assessment, would appear to be inadequately prepared as a nesting-ground for the fertilized egg.

### A Plan of Treatment

Basing treatment upon this evidence, I advise my patients to adopt the following plan:

1 To concentrate intercourse on their fertile dates, which can be calculated for them either mathematically as occurring on the 16th, 15th, or 14th day prior to the anticipated onset of a period (in a woman with a 28 day cycle these days will be the 12th, 13th, and 14th days from the first day of the last period) or, more accurately, by instructing them to assess the days by the early-morning temperature method.

2 To abstain from intercourse for a week or ten days prior to these fertile days which in practice amounts to abstaining from the first day of a period until the fertile days.

3 To take from the first fertile day 0.6 mg. of 'dienoestrol' and 10 mg. of 'ethisterone' daily.

4 To continue to take these hormones until the onset of the next period, when they are discontinued, since obviously the onset of a period indicates that on this occasion the attempt to aid nidation has failed. Should the period not start, the patients continue with these hormones daily until the 18th week of the pregnancy.

It should be noted that the administration of these hormones may delay the onset of the period by a few days even in the absence of pregnancy, but not longer. I quote the results of this treatment in 111 patients, in not one of whom could I discover any apparent cause for infertility by ordinary clinical examination. All of them had been sterile for more than two years, and 87 of them for periods varying between 3 and 10 years.

TABLE I—Cases in which there had been no Previous Pregnancies

Total number of cases	111
Failures	73 (65 8/)
Successes	38 (34 2/)
Analysis of failures	
Certain failures	37
No reply to letters of inquiry	36
Analysis of successes	
Pregnant in one month	13 (11 7/)
two months	4 (3 6/)
three months	6 (5 4/)
six months	15 (13 5/)
Number of miscarriages	3

It will be seen that within six months, to my knowledge, on medical treatment alone, 38 (34.2%) patients had become

pregnant. Three of these patients miscarried, but all the others gave birth to live babies.

Since this line of treatment can obviously have no influence upon obstructed tubes, it is not worth trying for more than a few months. I maintain, however, that it can influence the marriage which is sterile on account of poor spermatogenesis, as I shall attempt to show, and it is particularly useful in those patients who suffer from repeated miscarriages. Table II shows the results of the analysis of 38 cases in which there had been no difficulty in conceiving but merely in retaining the foetus. Not one of the patients whose records are shown in the Table had suffered from less than two miscarriages and not one had carried a baby to term.

This method of treatment has thus a wider application, particularly in two types of case—namely, (1) cases of repeated miscarriages, (2) cases in which a fault in the husband's semen is responsible for the infertility.

### Cases of Repeated Miscarriages

Many of such miscarriages appear to result from faulty nidation due either to a poorly prepared endometrium—that is, a fault in the environment—or to what can be described as poor germ-plasm—namely, a fault in the embryo. In fact, all causes of miscarriage must fall within these two categories, since Nature and Nurture, operating together, fashion the foetus—that is, embryonic development depends upon the interplay between genetic factors and factors imposed upon it by environment. A fault in either may result in impaired development or death of the embryo.

Many environmental causes of miscarriage are obvious and well known—for example, diseases of the maternal organism such as nephritis, hypertension, virus infections, etc. On the other hand, it is not so generally realized that inadequate endometrial preparation for nidation must be regarded as forming an adverse environment for the growth of the embryo, and thus it can be considered to be one of the environmental causes of miscarriage. This conclusion, however, is complicated by the fact that although the suitability or otherwise of the endometrium for nidation in the first instance is imposed upon the foetus—that is, it depends upon the activity of the corpus luteum—this is true only up to the moment of nidation, since from then onwards the continued activity of the corpus luteum and consequently the character of the endometrium depend upon a stimulus from the embryo itself. There is therefore a direct link between the genetical composition of the embryo and the continuation of the life of the corpus luteum.

Nature has in this way cunningly contrived that the intra-uterine environment shall be genetically determined, and has imposed upon the embryo the necessity to plough its own furrow.

This linkage between genetics and environment brings into consideration the father's contribution, and apportions to him part of the responsibility of ensuring an adequacy of the pregnancy hormones. The evidence obtained from the assessment of pregnanediol excretion rates suggests that a weak embryo means a weak stimulus (chorionic prolactin), and a weak stimulus a deficiency of the ovarian hormones, with a resulting poor environment and probable death and expulsion of the foetus.

Whether or not a fault in nidation is genetic (that is, a fault in the ovum) or environmental, a better environment—namely, a better-prepared endometrium—may make all the difference between success and failure. Just as in dealing with a delicate seed the husbandman prepares his soil carefully, so in order to facilitate the growth of the human ovum we should see that the endometrial soil is well

prepared before the seed is sown, and this can best be achieved by the administration of the pregnancy hormones (oestrin and progesterone) from the day of ovulation and consequently before it is known whether the patient is pregnant or not

Below, Table II shows the results of treatment of 38 cases of repeated miscarriage, for none of which was any apparent cause found. In all these cases rhesus incompatibility was excluded. It is a point of interest that in 30 of these cases the seminologist reported that the semen was subfertile, but, since it appears to me that seminologists have no normal standard on which to base such decisions, I do not think that any accurate conclusion regarding the semen can be drawn from these reports

TABLE II—Repeated Miscarriages

Total number of cases analysed	38
Number pregnant in 6 months	28
Live births	20
Miscarriages	6
Stillbirths	1
Spina bifida	1
Number not pregnant in 6 months	10
Previous miscarriages (96) among the 38 patients	
26 had had 2 miscarriages	52
8 " 3	24
4 " 5	20

## Results According to Number of Miscarriages

Two miscarriages	
Cases	26
Pregnant in 6 months	20
Living children	15
Miscarriages	5
Three miscarriages	
Cases	8
Pregnant in 6 months	6
Living children	4
Miscarriages	1
Spina bifida	1
Five miscarriages	
Cases	4
Pregnant in 6 months	2
Living child	1
Stillbirth at 8 months	1

Thus in six months 28 of these 38 patients were pregnant and 20 carried their babies through to term. Two were delivered by caesarean section.

## Infertility due to Inadequate Semen

Where we are dealing with a case of infertility in which we know that the semen is inadequate the same argument of preparing the soil to compensate for genetic weakness of the seed holds good.

Finally, there are two points in this plan which I would like to emphasize.

1 It has been shown by Allen (1932) and Leonard, Hisaw, and Fevold (1932) that progesterone proliferation of the endometrium will not take place unless it has been first sensitized by oestrin. It is for this reason that dienoestrol is administered in conjunction with ethisterone (progesterone). Also, it may be that the varying endometrial changes sometimes seen are due to an imbalance of these two hormones—that is, the endometrial response to progesterone is poor because there is not present at the same time an adequate oestrogenic secretion.

2 The hormonal treatment is continued until the 18th week and then withdrawn, since it has been shown by Browne, Henry, and Venning (1939) and others that there is a sharp rise in pregnanediol excretion about the 13th to the 16th week, and this increased excretion has been interpreted as signifying the commencement of elaboration of progesterone by the foetal chorion.

To continue to boost a pregnancy after this time, apart from being difficult and expensive, would appear to be eugenically unsound, since, if the foetus cannot elaborate enough hormones for the continuation of the mother's pregnancy, it might be a dysgenic act to allow it to live. Malpas (1942), Wenner (1941), and others have drawn attention to the fact that the incidence of foetal malformation is closely bound up with the problem of miscarriage,

and Wenner states that if a threatened miscarriage continues to term there is a greater than average chance of a deformed baby resulting.

During the recent war I was tempted on three occasions to give larger quantities of the ovarian hormones than is my custom and to continue them throughout the whole of the pregnancy. These three patients had threatened to miscarry before I saw them, and were bleeding when I first examined them, although uterine contractions were absent and urine pregnancy tests were positive. All three continued to bleed from time to time throughout the pregnancy, uterine growth was poor, and the breasts lacked serum.

After treatment of such patients for a week or two I would normally have withdrawn the hormones and allowed the miscarriages to take place. These three patients, however, were elderly primigravidae, and their husbands were going on service abroad and were not likely to return in time to make further conception possible. I therefore continued to administer large quantities of hormones throughout the pregnancies in spite of repeated bleedings, slowly growing hard uteri, and poor breast changes. All three terminated their pregnancies by premature labour between the 30th and 35th weeks, and all three gave birth to abnormal babies, not one of whom survived. Two of the babies were cases of exomphalos and one was a case of microcephaly, and the labour was accompanied by bleeding from a placenta praevia.

I therefore now discontinue administering the hormones at the 18th week, at which time the function of the corpus luteum is over and the hormones should have been elaborated entirely by the embryo itself. The embryo should, as it were, stand on its own feet from then onwards.

To continue to treat a case of threatened miscarriage in spite of repeated bleedings can be likened to watering a garden when a plant is withering. The damage has already probably been done and we are unaware of the direction in which the embryo is developing. In most cases it would be advisable to allow the miscarriage to complete itself and start again with an endometrium adequately prepared—that is, to sow the seed in better soil by adopting the plan which I have outlined above—since a good start means good roots and good roots a good superstructure (the foetus). For this reason it does not appear to me to be unwise to aid the embedding and early growth of the embryo, but once the stage is reached at which large quantities of hormones are necessary and at which they are elaborated entirely by the foetal chorion I think that in the interest of eugenics the help should be withdrawn.

Embryos of all animals lower than the mammals have a very uncertain environment, for which they are compensated by multi-egg spawning. The environment of the mammalian embryo, however, is so potentially safe that were some check not placed upon it many abnormalities might survive. Nature, however, has determined that mammalian embryonic environment shall be genetically controlled, and thus those embryos which fail to elaborate enough hormones for their own survival are discarded. In the present state of our knowledge of embryonic growth it would seem to be unwise to run counter to this principle.

# RINGWORM OF THE SCALP IN THE EASTERN REGION OF SCOTLAND, 1946-7

BY

J KINNEAR, MD, MRCP Ed

Lecturer on Skin Diseases University of St Andrews

AND

JOHN ROGERS, MB, Ch B, BSc

The main object of this paper is to present a picture of ringworm of the scalp in the Eastern Region of Scotland (counties of Angus and Perth) from July 1, 1946, to the end of 1947. During this period there were two epidemics of small-spore ringworm and 631 cases were seen. Owing mostly to lack of appreciation of the factors involved, misleading or doubtful statements are still being made about ringworm of the scalp, and the opportunity is here taken to make categorical statements when these appear justified. Some experiments with local treatment are described.

The great majority of cases of ringworm of the scalp in this country are due to microsporon infection, but as one travels south through Europe the proportion changes till in Italy nearly all cases are due to the trichophyton (Walker and Percival, 1939). Recent reports confirm this statement. Keddle (1947) found in an epidemic of scalp ringworm in Bathgate, Scotland, that all the 351 children were infected by microsporon. Chmel (1946), in analysing results of cultures from 156 cases of ringworm, not confined to scalp cases, in Czechoslovakia from 1942 to 1946, found that microsporon was responsible for 40% (he states that the number is still increasing), *Trichophyton endothrix* 22.4%, *T. ectothrix* 26.9%, *Achorion* 2.56%, and *epidermophyton* 8.14%. Catanei (1947) states that out of 871 cases of ringworm in school children in Algiers examined in 20 years 4.5% were due to microsporon (*M. canis* more often than *M. audouinii*), 9.5% were favus, and the remaining 86% *T. endothrix* infections.

In the U.S.A., reports of several epidemics have recently been published showing an overwhelming preponderance of microsporon infection of the scalp. Schwartz *et al* (1946) found *M. audouinii* in all but 8 cases out of 565 in Haverstown, Maryland, during 1944-5. Lewis *et al* (1946) saw in the New York Hospital 312 patients with tinea capitis from July 1, 1943, to June 30, 1945, 305 were microsporon infections (*M. audouinii* 275, *M. lanosum* 30), 5 were due to *T. endothrix* and 2 to *Achorion*. Over 28 months to May, 1945, out of 928 cases in the Vanderbilt Clinic Miller *et al* (1946) found 96.9% due to *M. audouinii*, 2.6% due to *M. felineum* (*M. lanosum*), and only 0.5% due to other organisms.

With regard to the type of microsporon found in this country, Duncan (1945) states that *M. audouinii* seems to be the predominant species causing tinea capitis in the Midlands and North, while the animal types were common in school-children in the southern counties and in the London area. In the latter area the two types of microsporon were found in approximately equal numbers.

Favus was formerly common in Scotland. McCall Anderson (1871) found it in 1.56% of 10,000 consecutive dispensary cases in Glasgow. Norman Walker (1899) stated that the opportunities of studying favus were numerous in Scotland. As will be seen, it is now rare in the part of Scotland under consideration, though cases continue to crop up occasionally.

## Two Epidemics of Ringworm

Fig 1 shows the occurrence of ringworm of the scalp as seen in the ringworm clinic of Dundee Education Authority from its inception in 1914 to the outbreak of

the last war. It will be seen that the infection had almost disappeared from this area by September, 1939. Its recrudescence is simply explained by war conditions: mass movement of children in evacuation schemes and consequent relaxation of supervision by parents and school medical staffs allowed an endemic condition to become epidemic.

Fig 1—Incidence of scalp ringworm in Dundee from 1914 to 1939

In this region there have been two recent major epidemics of ringworm of the scalp—one in Dundee (population 180,000), which first appeared in 1944, and one in Arbroath (population 18,000), some fifteen miles away, in which cases were first noted in the middle of 1946. Fig 2 shows the progress of these epidemics.

Fig 2—Progress of epidemics in Dundee and Arbroath (1946-7)

Before the return of one of us (J.K.) from war service considerable difficulty was experienced in dealing with the Dundee epidemic. Adequate facilities for x-ray epilation were not available and thallium had been procurable only in inadequate quantities when it had been available at all. From the middle of June, 1946, however, the epidemic could be tackled satisfactorily, and when asked to deal

with the subsequent epidemic in Arbroath we were able to arrange at once for the requisite organization and facilities

From July 1, 1946, to the end of 1947 Dundee produced 217 cases, in Arbroath there were 381, while from other parts of the region we received 33—a grand total of 631 cases

### Mycology

Owing to scarcity of Sabouraud's original medium and the difficulty of classification with any modification, not all the cases were examined culturally. By random culture from cases considered typical of infection by *M. audouinii* and routine investigation of all the rest we were able to satisfy ourselves that any error in clinical diagnosis put the more inflamed audouinii infections among the animal ringworms, never the reverse

TABLE I—Type of Infection

	Micro sporon		T. endothrix		T. ectothrix (Clinical)	Ach. scd'n	Total
	Aud	Lan	Crater	Sulphur	(Clinical)		
Dundee	202	8	5	1	1	—	217
Arbroath	381	—	—	—	—	1	381
Rest of region	30	—	—	—	—	2	33
Total	613	8	5	1	1	2	631

Table I shows the types of infection found and the very great preponderance of *M. audouinii* infections—97.1%. In all, 98.4% were microsporon infections

In Dundee 183 cases were in boys and 34 in girls, in Arbroath the figures were 322 and 59 respectively, while from the rest of the region there were 26 boys and 7 girls. This gives a proportion of 84.15% boys and 15.85% girls affected. Keddie (1947) found 89% boys affected and 11% girls out of 381 cases, Schwartz *et al.* (1946) give 84.4% boys and 15.6% girls among their 565 cases, so that the figures from this country and from the U.S.A. for similar epidemics are almost exactly the same. Fig. 3 shows the age and sex incidence in the Dundee and Arbroath epidemics

Fig. 3—Age and sex incidence in combined epidemics. Not shown in the Graph are ages 0-5 years: boys 72, girls 33, total 105 cases

The marked prevalence of the infection in boys in the clipper area—that is, the area so dealt with in barbers' shops—had been commented on by Schwartz *et al.* (1946). They found 65% of boys were affected in this area alone, 21% in the clipper area and elsewhere, and 4% on the crown. In girls the commonest site was the parting of the

hair. Table II shows the site of the primary lesion in the Dundee and Arbroath epidemics. In the case of the disseminated infections it was impossible to ascertain accurately where the disease started, but the clipper area was always included. The cases affecting the eyebrows were interesting. Here typical lesions of *M. audouinii* infection of the glabrous skin were seen, including in their orbit parts of the eyebrows. Examination under Wood's light showed the typical fluorescence of the eyebrow hairs within the infected areas. Lesions of the hair margin showed fluorescence of the lanugo hairs as well as of the scalp hairs within the lesion.

TABLE II—Site of Original Lesions Dundee and Arbroath Epidemics

	Boys	Girls
Occipital region	56%	32%
Parietal region	9%	17%
Vertex	4%	16%
Frontal region	2%	6%
Hair margin	4%	6%
Disseminated	25%	21%
Eyebrow only	1 case	2 cases

In boys the most prominent part of the occiput was the one most frequently involved. This led one to incriminate as the source of spread something with which this part in particular came in contact, such as the back of cinema seats, but no definite proof could be obtained that they were at fault. Barbers' shops are a more likely source of spread. Few barbers sterilize the tools of their trade between customers, and scissors, clippers, combs, and brushes can easily pick up infected particles of hair and pass them on to other scalps. Girls are not so exposed to this risk, and their long hair affords a considerable degree of protection from infection. This is shown by the fact that the more easily accessible portions of the scalp about the parting of the hair are most often involved, as Schwartz remarks.

### Organization

To control ringworm infection it is essential that efficient organization and liaison exist. Any case of ringworm of the scalp should be notified to the school medical officer concerned so that all possible contacts can be examined by Wood's light and missed cases discovered. By this means other epidemics have been nipped in the bud, and by the end of the period under review ringworm seems to be well under control throughout the whole of the region. For instance, in one small town a game of blind-man's-buff resulted in four girls developing ringworm in the area which had been in contact with the handkerchief. The source of infection was known and further spread was prevented. A pupil in a private girls' school was found to have ringworm. She had recently returned from India, where she had had ringworm but had been pronounced cured by her doctor. On being informed the school medical officer visited the school by arrangement and examined all the girls under Wood's light. Three other girls were found to be infected, but though this examination has been repeated there have been no further cases. A boy in hospital suffering from paralysis following anterior poliomyelitis was observed to be infected. He had passed the disease on to two other boys in the ward, but his history showed that he had had the infection before admission. The school medical authorities visited his home town and found among his class at school three other cases.

School medical authorities should have a portable source of Wood's light and a staff trained in its use. The immediate examination of all possible contacts, treatment of any case found, and repetition of the examination made till a period of at least three months has elapsed since the last case was discovered will ensure extermination of the outbreak.

For the investigation of children under school age one has to depend on the co-operation of the parents, but they

are as a rule very willing to have their children examined. The demonstration of a vividly fluorescing head creates a very strong impression on parents.

For treatment accommodation provided with Wood's light and a trained staff is essential. Cases were seen by us weekly, but manual epilation where required was done by the nursing staff. They soon grew very proficient in the detection of infected hairs and in their removal. Skilled fingers will remove many an infected hair which would break off under less adept hands.

Recording must be carefully done not only to provide a record of treatment but to keep a check on attendance so that absentees can be rounded up. Although attendance of patients was on the whole satisfactory, carelessness had to be checked and absentees induced to return by visits to their homes to explain the necessity for regular attendance not only for the child's sake but for that of others who might be infected by him.

The running of the clinics was under our supervision, for it is very necessary that a trained dermatologist should oversee the treatment. Ringworm of the scalp varies so much in its manifestations that the many problems that crop up can be solved only by one experienced in dealing with ringworm.

No child was allowed to return to school until given permission by the dermatologist. Without the use of Wood's light it is impossible to be certain that all infection by microsporon has gone. Many cases have been seen in which clinically no evidence of infection remained and yet under Wood's light the tell-tale fluorescence showed that the disease was still present. It should be stressed to all general practitioners that this is the only certain method of assessing cure and preventing children still infected being allowed back at school.

### Clinical Varieties of Scalp Ringworm and Their Diagnosis

The various types of ringworm must be considered separately, they present different problems in diagnosis and require different forms of treatment.

*Small spore Ringworm*—All cases of this infection showed characteristic fluorescence under Wood's light. This appears to be common to hairs affected by different species of microsporon, but in addition by this means information can be obtained about the age and state of the infection.

*M. audouinii*—Recent infection showed well-defined circular areas within which the hairs fluoresced bright green. Sometimes the hairs at the margin were more evident than those at the centre, they had not been broken off so short. In such cases total epilation by x rays or by thallium is the most rapid and certain means of cure. The infection is virulent and likely to spread. In older infections the patches are not so well defined and the fluorescence may not be so vivid—whitish rather than green. There is often a more pronounced scaly reaction of the skin than in new infections and there is not the same tendency to spread. The fungus appears to have lost some of its virulence and is more amenable to treatment by local epilation by x rays or even to local application of a fungicide and manual epilation. The hairs are not so brittle as in a recent infection and can often be epilated whole.

Occasionally, especially after thallium epilation, a few hairs remained infected in an attenuated form. These hairs may be of normal length and show an interrupted fluorescence giving rise to a beaded appearance under Wood's light. It was usually possible to epilate such hairs completely. If a hair broke below the surface of the scalp a scale was apt to grow over the follicular orifice and hide the stump. Consequently there was no green fluorescence under Wood's light till the scale had been removed when the vivid green of the growing stump became visible. Any scale must be removed and the underlying scalp inspected before one can be certain of cure.

Sometimes a case of *M. audouinii* infection showed a kerion reaction. If one lesion became affected, all did. These crises were apt to be mistaken for animal microsporon infections but culture showed the characteristics of *M. audouinii*. The development of kerion in these cases is spontaneous and not affected by any form of treatment used. It may be active enough to cause spontaneous fall of the affected hairs and consequent cure, but is less likely to do so than in the case of infection by *M. lanosum*. Out of the 381 Arbroath cases 24 showed this kerion formation—15 were cured by local measures and 9 required x ray epilation.

*M. lanosum*—At first this infection is clinically indistinguishable from that due to *M. audouinii* but in all cases seen a follicular inflammatory reaction occurred, probably at least a fortnight after the first appearance of symptoms, leading to mild kerion formation, usually with desquamation of the patches and cure. This could be helped by manual epilation of the affected hairs under Wood's light. Sometimes these crises were given x rays before the onset of kerion, this seemed to have little influence on its progress. The kerion did not seem to be made worse by x ray treatment.

The degree of kerion produced by microsporon infections is much less than by *T. ectothrix* and no sequelae such as permanent loss of hair or scarring were noted. The appearance of this reaction is therefore beneficial and it is regrettable that so far no satisfactory method of producing it artificially has been devised.

*T. ectothrix*—In view of the small number of cases seen there is little to say about this infection. Careful examination under Wood's light failed to show any fluorescence of the affected hairs. No case resembling a condition which could be called 'black dot ringworm' was seen. The clinical appearance in all cases was an irregular area showing loss of hair with some scaliness and with broken hairs scattered between those of normal length. Scrapings from the affected area examined in liquor potassae under the microscope revealed among the scales fragments of hair containing the typical chains of squared spores. Local epilation of the affected areas by x rays was sufficient to cure the condition.

*T. ectothrix*—Only one case is included in this series. Owing to the length of time the disease had existed no affected hairs remained and culture from pus and crusts was negative. The kerion was typical of this type of infection, a well defined swollen, inflamed area oozing pus from dilated follicular openings. The child came from a farm where cattle were infected with ringworm. During the period under review we have seen only one case of ectothrix kerion in which affected hairs remained, and on careful examination under Wood's light no fluorescence of the hairs was noted. In this case *T. gypsum asteroides* was the fungus responsible. Fortunately Wood's light is not essential for the management of such cases; the clinical picture is adequate guide for diagnosis and estimate of cure.

*Favus*—The two cases in this series were in brother and sister who lived in the country. The disease had existed for over a year and had been diagnosed as seborrhoeic. The mother had been conscientious in her treatment, which consisted in regular washing and application of ointment; consequently no scutula were seen and there was little alopecia. The picture was of well-defined patches of inflammation of the scalp especially round the follicles. The scalp in the affected areas was red and rather scaly, there was slight patchy cicatricial alopecia, but no broken hairs were seen. The margins of these areas were sharply defined. Favus was suspected on account of the above characteristics and the occurrence in two members of the same family. There was also a distinct mousy odour about the scalps. Under Wood's light the diagnosis was easily confirmed, and the extent of the infection was found to be much greater than had appeared at first sight. There were numerous unsuspected small areas of infection. Achorion infection can readily be distinguished from microsporon infection under this light. The fluorescence is a dusty green quite different from the brilliant green fluorescence of microsporon infected hairs. A still more distinctive characteristic is that the hairs are not broken off short but are more or less of normal length. The combination of long dusty green fluorescing hairs on a scalp inflamed and red in colour showing alopecia with

scarring occurring in well-defined patches is pathognomonic of favus and enables a diagnosis to be made even in the absence of scutula. Chronic impetigo of the scalp, the lesions remaining in the same situation for more than a few weeks, should always lead to a suspicion of favus.

It may be mentioned that during the period under review two cases of favus of the glabrous skin were seen. Both showed typical scutula. One of these patients, a boy, had lesions on his abdomen, the other, an adult female, was affected on the left upper arm. In the latter case *A. quinquaneum* was the responsible fungus.

### Treatment

Epilation by x-rays or thallium was employed in all cases of microsporon infection except (a) cases showing kerion formation in which local treatment was given a chance first—and only if there was likelihood of insufficient spontaneous epilation were other means used, (b) those with attenuated old infection—in these cases also local applications and manual epilation were used and (c) children under 2 years old, because it was not thought desirable to use thallium at such an early age, and because, the hair follicles being relatively shallow in young children, the disease is more amenable to local treatment. It was found, however, that at best these cases took longer to cure than those which were epilated by thallium or by x-rays.

In all 93 cases were cured without x-ray or thallium epilation—a percentage of 14.74. Lewis *et al* (1946) state that there is a tendency to spontaneous recovery in approximately 10% of patients. The remainder underwent x-ray or thallium epilation. All children under 7 years of age who were unlikely to remain still enough for satisfactory x-ray treatment received thallium. Beyond transient and mild symptoms there were no bad effects from this drug. Strict precautions were taken for its administration, weighing was done by a nurse and checked independently by a doctor, who wrote out the prescription for the dose, using Ingram's method to calculate the amount required—i.e., multiplying the weight in pounds by four to get the dose in milligrams. The dose was made up in orange squash and given to the child and drunk in the nurse's presence. No difficulty was experienced in inducing the child to take the dose in this way. It was not regarded as 'medicine'.

In view of the large numbers to be dealt with, x-ray epilation of local patches was used in selected cases to save time. At first all the cases so chosen were probably not suitable, and the treatment had to be extended in some cases as the disease had spread. Later more careful selection made this method more successful.

Thallium epilation is not so complete as that following x-rays and considerable trouble was experienced when all the affected hairs did not fall out. Treatment had then to be continued by manual epilation and in some cases thallium had to be repeated or x-rays used to obtain a cure. Six months were allowed to elapse before thallium was repeated, and no bad effects were encountered, in fact, some children showed more reaction after the first dose of thallium than after the second. Details of treatment are given in Table III.

TABLE III—Treatment (in Addition to Manual Epilation)			
1. X-rays only	93	Total x-rays repeated	2
2. Thallium	197	Thallium	77
3. Thallium repeated	10	Thallium repeated	6
4. Thallium then x-rays	25	Thallium then x-rays	16
5. X-rays	20	Refused all treatment	2

Ointments were used in preference to liquid applications. The greasy nature makes infected particles less likely to be rubbed off and infect others. Iodine was not used, it coats the scalp so that they appear jet-black under Wood's light and if presence is obscured. Whitfield's ointment was employed as a routine but if kerion was present it was

replaced by 1% ammoniated mercury in petroleum jelly. Through the kindness of ICI (Pharmaceuticals), Ltd, a supply of salicylanilide ointment as recommended by Schwartz (1946) was obtained. The formula used was

Salicylanilide	4.5
Cetavlon	1
Carbo wax 1500	to 100

In addition salicylanilide in "eucerin" base and in alcohol were used, and latterly sodium salicylanilide.

Parents were instructed to apply the ointment to the whole scalp daily, to wash it twice weekly, and to keep it covered with a cotton cap. When the hair began to fall it was to be assisted by daily pulling out the loose hair with the object of completing the epilation as rapidly as possible. Patients attended the clinic weekly during this period so that the epilation could be supervised. This is extremely important, as parents varied in their efforts to extract the loose hairs.

Schwartz (1946) found it difficult to show statistically the advantage of salicylanilide in carbo-wax over other applications, but it was undoubtedly present, though we find ourselves in the same position. Those who had to deal with the epilation of the hair in the various clinics were unanimous in their opinion that it was the only application which seemed definitely to assist in cure. Under its influence hairs were more easily epilated and more likely to come out whole than with other ointments. The greater penetrative power of the carbo-wax was apparently the important factor, as salicylanilide in eucerin base was no more effective than other ointments, and salicylanilide in alcohol was found to give a similar result. Sodium salicylanilide was disappointing and less effective than salicylanilide.

It is important to remove any ointment before examination under Wood's light, as vaseline fluorescence obscures that of ringworm. Carbo-wax is non-fluorescent, but sodium salicylanilide, unlike salicylanilide, fluoresces blue, not unlike vaseline. It was found that by passing the light through a lens not only was its intensity increased but much of the vaseline fluorescence was removed without altering the fluorescence of the affected hairs. Lenses were used both in this way and to examine the scalp to facilitate the identification and removal of faintly fluorescing hairs and short stumps.

Four weeks after x-ray or thallium administration the scalp was normally clear of infected hairs and the child was allowed to return to school. Supervision was continued for a further six weeks, and the child was re-examined in a fortnight and again in four weeks. Occasionally an odd fluorescent hair was detected at these examinations, this was usually easy to remove completely. In this case the child reported again in four weeks. By the end of that period the hair had started to grow again and its progress could be noted. A satisfactory regrowth was obtained in every case except those of favus and ectothrix infection which showed some trace of permanent baldness.

Regrowth of the hair after x-ray epilation often shows an increase in curliness over its previous condition. The number of curly-headed boys in Arbroath was at one time noteworthy, but to the relief of most of them this state is only temporary, and the hair gradually resumed its former condition and the curls disappeared in the hairdressers' shops.

### Summary and Conclusions

After a review of the occurrence of ringworm of the scalp in Europe and the United States of America a summary of the incidence of this disease as seen in Dundee from 1914 to 1939 is given. Cases seen in the Eastern Region of Scotland from

July 1, 1946, to Dec 31, 1947, are analysed and show that, including two major epidemics during this period out of 631 cases 98.4% were microsporion infections (97.1% *M. audouinii*) and 84.15% were in boys. These figures correspond closely to recent figures from other parts of Scotland and from the U.S.A. Infection most commonly appeared to occur in barbers' shops.

Wood's light was found essential in the diagnosis and management of microsporion and favus infections but of no use in trichophyton cases.

Epilation by x rays or thallium is still the most rapid and successful means of cure but fungicides assisted by a wetting agent in carbo-wax 1500 offer a chance of cure in at least a fair proportion of cases after a considerably longer period of treatment. It must be realized that especially with the animal microspora, a modified kerion reaction may occur leading to spontaneous cure, so that in assessing the value of any 'cure' for ringworm the actual fungus causing the condition and the criteria of cure must be known.

A brief note is made of the organization required for a centre to deal with cases of ringworm and the standards necessary for ensuring that patients are non-infectious before their return to school.

## CIRRHOSIS OF LIVER PRESENTING AS SEVERE ANAEMIA

### REPORT OF TWO CASES

BY

P. N. COLEMAN, M.B., Ch.B.

Pathologist Townleys Hospital Bolton Lancs

This paper concerns two cases of cirrhosis of the liver in which a severe anaemia, thought to be haemolytic, was the predominant feature. Both cases were sent to hospital because of anaemia, and cirrhosis of the liver was not diagnosed until after further investigation, in the second case not until necropsy. They are reported because haemolytic anaemia is said to be an uncommon complication of cirrhosis.

The anaemia accompanying cirrhosis of the liver is described as normocytic or macrocytic, and haemolysis is not a feature. The anaemia is seldom severe. Macrocytic cases resemble pernicious anaemia in some features (Whitby and Britton, 1946; Wintrobe, 1936; Wintrobe and Shumacker, 1933; Singer and Dameshek, 1941).

Davidson and Fullerton (1938) report a case of a macrocytic haemolytic anaemia in cirrhosis in which red-cell fragility was increased. Watson (1939), from studies of urobilinogen excretion, emphasizes that in some cases of cirrhosis a haemolytic element is present. He describes seven out of 38 cases of cirrhosis studied in which there was evidence of haemolysis. One of these had two severe haemolytic crises, during the second of which the patient died. Haemoglobin fell to the low level of 25%. Necropsy

revealed a diffusely cirrhotic liver, which on section showed portal cirrhosis. The liver was described as quite fatty. Femoral marrow was red.

Singer and Dameshek (1941) include disease of the liver among the relatively few conditions that can give rise to symptomatic haemolytic anaemia. They describe a case of subacute hepatitis in which a severe haemolytic anaemia was an important symptom. The haemoglobin fell to 27%, there was marked reticulocytosis, sternal puncture revealed a normoblastic hyperplasia, the anaemia was macrocytic and fragility was normal.

#### Case 1

The patient, a man aged 66, was admitted to Townleys Hospital on Oct. 2, 1947, because of extreme pallor and shortness of breath. He had been working as a lorry driver up to three weeks before admission. He gave a history of vague abdominal pain and lack of appetite for several months. He had been a heavy beer-drinker for 30 years. He was extremely pale with an icteric tinge. Liver was enlarged to the umbilicus and the spleen was palpable two fingerbreadths below the costal margin. A blood count showed Hb, 18%, red cells 890,000, C.I., 1. The red cells appeared normal in size and shape. Biochemical findings supported a diagnosis of cirrhosis of the liver. The van den Bergh test gave a positive direct reaction, total serum bilirubin was 2.6 mg per 100 ml. Thymol turbidity was 12 units. Serum globulin was raised to 4.1 g per 100 ml, serum albumin was 3.3 g per 100 ml, and the albumin-globulin ratio was reversed. Urine gave a strong reaction for urobilinogen and contained a trace of bilirubin. Tests for occult blood in the faeces were negative on three occasions.

The patient received a series of blood transfusions until he died 21 days after he was admitted to hospital. Although he showed no obvious reaction to these transfusions it soon became evident that the transfused cells were rapidly destroyed because the rise in haemoglobin obtained was very small. Twelve days after admission to hospital he had received 11 pints (6.25 litres) of blood and his haemoglobin had varied between 28 and 35%. Shortly before he died he received the packed cells from 3 pints (1.7 litres) of blood and the haemoglobin was raised to 45%.

At necropsy the liver was of normal size and showed a diffuse cirrhosis. The spleen was enlarged to twice normal size. Section showed a portal cirrhosis with the architecture of the lobules destroyed by numerous bands of young fibrous tissue insinuated between the liver cells. There were considerable deposits of iron pigment in the liver and spleen.

#### Case 2

A woman aged 58 was admitted to Townleys Hospital on April 1, 1948, because of pallor and dyspnoea. She gave a history of vague ill-health for over a year and had recently had a small vaginal haemorrhage. She had been living on a very poor diet for a long time and said the only thing she really cared for was a glass of beer.

On examination the patient was pale, slightly icteric, and looked very ill. There were purpuric spots on forearm, thighs, and buttocks. She was obese but it was thought that a tumour (? liver) could be felt in the right hypochondrium. Pelvic examination revealed nothing abnormal. The blood count on admission was as follows: Hb, 29%, red cells 1,410,000, C.I. 1.03, reticulocytes, 22.5%, white cells 4,600, normal differential, platelets, 160,000, bleeding and clotting time normal. There was a little anisocytosis, but the majority of red cells appeared normal in size. Five orthochromatic normoblasts were seen while counting 100 white cells. Biochemical findings were as follows: van den Bergh test gave a positive direct reaction, serum bilirubin 3 mg per 100 ml, direct indirect quotient (Gray, 1947) 68. Thymol turbidity was normal (4 units), alkaline phosphatase normal (10 units), and urine gave a very strong reaction for urobilinogen and contained a trace of bilirubin. No occult blood was found in the stools. The patient was given 3 pints of blood, which raised her haemoglobin to 55%, but her clinical condition showed

very little improvement. A week after the transfusion a fragility curve (Creed's method) showed a definite increase in fragility the haemolysis in 0.5% saline being still 8%. Patient died 11 days after admission to hospital.

Post mortem findings were as follows: the liver was slightly larger than normal and showed cirrhosis. The colour was a green brown and the surface was covered with small nodules. The spleen was congested and enlarged to twice the normal size. Section showed a portal cirrhosis with young fibrous tissue breaking up the lobules. There was infiltration of the fibrous tissue with lymphocytes. Quite a large proportion of the liver cells were distended by globules of fat. There were deposits of iron in the liver and spleen. The femoral marrow was red throughout its length and showed a normoblastic hyperplasia.

### Discussion

In both cases a severe anaemia has to be explained. Haemorrhage can be discounted. Tests for occult blood in the stools were negative. In the first case there was no history of bleeding, in the second there had been a small vaginal haemorrhage and purpuric spots, but nothing which could account for a haemoglobin of 29%. The appearance of the blood films was quite unlike that of pernicious anaemia. Case 1 received an urgent blood transfusion on admission and a reticulocyte count was not done, but there is evidence of a haemolytic process in the remarkable behaviour of this case on transfusion. A total of 14 pints (8 litres) of blood was given to this patient over a period of 14 days and relatively little increase was obtained in the haemoglobin. This can be explained only by a rapid destruction of transfused cells, which is one of the features of haemolytic anaemia (Sharpe and Davis, 1938). In the second case there is clear evidence of a haemolytic anaemia: a high reticulocyte count, numerous nucleated red cells, increased fragility, and red marrow in the shaft of the femur.

The biochemical findings do not assist in the diagnosis of the anaemia. The positive direct van den Bergh reaction and the presence of bilirubin in the urine are not, of course, the findings of haemolytic jaundice, but can readily be explained on the basis of the coexistent liver damage. The large amounts of urobilinogen in the urine are more likely to be due to the cirrhosis than to the haemolysis.

My thanks are due to Dr E. S. Gawne, medical superintendent, Townley Hospital for permission to publish these case reports, and to Drs D. Mooney and R. Kearney for the opportunity to co-operate in the diagnosis and treatment.

## TREATMENT OF ABORTUS FEVER WITH SULPHONAMIDES AND BLOOD TRANSFUSIONS

BY

J. MacD. HOLMES, M.D., M.R.C.P.

Physician, Staffordshire General Infirmary,  
Consulting Physician, Crewe and District Memorial Hospital

AND

ROBERT HUGHES, M.D., M.R.C.P.

Visiting Physician, Clatterbridge (County) General Hospital  
Honorary Assistant Physician, Royal Liverpool United Hospital  
(Royal Southern Hospital Branch)

The treatment of undulant fever has remained unsatisfactory in spite of recent advances in chemotherapy, although occasional successes have been reported from the use of sulphonamides, suramin, vaccines, and injections of brucellin. Recent reports of treatment with penicillin and streptomycin are also very disappointing. In an annotation in the *British Medical Journal* (1947, 2, 700) attention was called to a report by Huddleson, made to the Fourth International Congress for Microbiology at Copenhagen in July, 1947, of four cases of undulant fever which responded quickly to the administration of small doses of sulphonamides together with blood transfusions. No special care was given to the selection of donors, it was assumed that all human serum contains bactericidal brucella antibody, but it is difficult to understand why a weak antiserum in conjunction with a sulphonamide should have a bactericidal effect. Huddleson explains this on the basis of the Neisser-Wechsberg phenomenon—a serum may be bactericidal in high dilution yet not in low dilution.

This method of treatment was tried in two cases of undulant fever with the encouraging results indicated in the following reports.

### Case 1

The patient, a woman aged 32, first complained of feeling ill about Dec. 16, 1947. A week later she was found to have an evening temperature rising to 102° F (38.9° C). She was seen by her doctor on Jan. 17, 1948, when she complained of tiredness, headaches and pain in the back. On examination at this time her temperature was 100° F (37.8° C) and her pulse rate 86 per minute; she had lost a little weight and her spleen was much enlarged.

On Jan. 8 she was admitted to Clatterbridge (County) General Hospital where re-examination confirmed the above findings. Her evening temperature ranged from 100.4° to 102.6° F (38°-39.2° C) but apart from the fever and the splenic enlargement no abnormality was found. On Jan. 19 the blood urea was 26 mg per 100 ml. A blood count showed red cells 5,000,000 per cmm, haemoglobin 92%, white cells 3,600 per cmm (polymorphs 52.5%, lymphocytes 45%, monocytes 2.5%). Agglutinations positive in all dilutions up to 1:1,400 against *Br. abortus*, negative against *Salm. typhosus* and *paratyphosus*. The urine was free from sugar and albumin. Blood culture contaminated by *Staph. albus* (coagulase-negative); no other organisms found. X-ray film of the chest was normal. Blood Wassermann reaction was negative.

The following treatment was given: penicillin 9 mega units (Jan. 25 to Feb. 31), sulphadiazine, 75 g (Feb. 7 to 19), and blood transfusions of 10 oz. (280 ml) on Feb. 11, 13, 15, and 17. There was no clinical improvement with penicillin, but once the sulphadiazine and transfusions were begun the temperature rapidly subsided and the patient's condition improved. She was discharged from hospital on Feb. 26 and reported to the outpatient department on April 14. She had been afebrile since discharge, felt well in every way, and there was no splenic enlargement.

The Government of Cyprus has recently celebrated the 25th anniversary of the establishment of the Department of Health, which the authorities were chartered to report the progress of the Department in 1946 and is aimed at the eradication of malaria from the island by 1952. The Department is a difficult one to work in, with its many problems and rushing streams. *Aropheles superciliosus* is a common and rock pools are almost inaccessible. The Department is divided into zones which are systematically surveyed by D.D.T. in oil.

The following are the results of further investigations  
Feb 19 —Blood count red cells 4,380,000 per cmm, haemoglobin, 87%, white cells 5,200 per cmm Agglutinations negative in dilutions of 1 25 and 1 50 against *Br abortus* positive in dilutions of 1 125 1 250 and 1 1 250  
April 16 —Blood count haemoglobin, 95% red cells, 4,680 000 per cmm, white cells, 6 600 per cmm (polymorphs 68%, lymphocytes 30%, monocytes 1%, basophils 1%) Agglutinations negative in dilutions of 1 25, 1 50, 1 250 and 1 1 250 against *Br abortus*, positive in dilution of 1 125

### Case 2

This patient, a woman aged 38 first complained of feeling ill on Jan 24 1948 She had shivering, sweating, headache, and pain in the right ear On examination she was found to have an evening temperature swinging to 102° F (38.9° C), but no other abnormality was found On Feb 8 a blood count showed haemoglobin, 84%, red cells, 4,690,000 per cmm white cells, 4,000 per cmm (polymorphs 46%, lymphocytes 49%, monocytes 4% basophils 1%) Agglutinations positive in all dilutions up to 1 500 against *Br abortus*

The following chemotherapy was given sulphamezathine, 48 g (Feb 2 to 5 and 9 to 11), penicillin 1 200 000 units (Feb 9 to 11) and sulphadiazine 51 g (Feb 27 to March 3) Despite this treatment the patient's condition deteriorated, she had distressing rigors with profuse sweating and pyrexia rising to 105° F (40.6° C)

On March 4 she was admitted to the Staffordshire General Infirmary She was still seriously ill, the temperature rising to 104° F (40° C) and the spleen was slightly enlarged Treatment with sulphadiazine and blood transfusions was begun on March 5, as follows sulphadiazine, 30 g (March 5 to 9) and 6 g (March 13), blood transfusions, 10 oz (280 ml) (March 5), 15 oz (425 ml) (March 8) and 4 oz (110 ml) (March 13) The patient felt much better after the first transfusion and there was an immediate lessening of the severe rigors and sweating She was discharged from hospital afebrile on March 18

She felt well and remained apyrexial until April 6, when she developed pain under the right costal margin and a temperature of 102° F (38.9° C) a diagnosis of acute cholecystitis was made and she was readmitted to hospital on the following day The condition showed no signs of settling despite 25 g of sulphadiazine over a period of four days, and finally a cholecystectomy was performed by Mr B R Sworn on April 19 The gall-bladder was acutely inflamed and a pure culture of *Br abortus* was obtained from the contents

There was some increase in the pyrexia and malaise after the operation so it was decided to try further treatment with sulphonamides and blood transfusions Sulphadiazine, 12 g (April 22 and 23) and 6 g (April 27), and blood transfusions, 8 oz (225 ml) (April 23) and 6 oz (170 ml) (April 27) were given There was a mild reaction to the second transfusion, a rigor, and transient rise of temperature, but immediately afterwards the pyrexia subsided completely and the patient said that she felt better than she had been throughout the whole illness She was discharged from hospital on May 5 and has since remained well

### Comment

Both these cases of abortus fever had failed to respond to ordinary chemotherapy Case 1 did not improve with penicillin and Case 2 was not affected by penicillin, sulphamezathine, or sulphadiazine In each case there was rapid response to sulphadiazine and small blood transfusions Case 2 returned three weeks later with acute cholecystitis due to *Br abortus*, the temperature did not subside following cholecystectomy but responded to further sulphadiazine and blood transfusions

While it is impossible to draw conclusions from only two cases, we feel that these results are encouraging and that this method of treatment should be given a more extended trial

Our thanks are due to Dr D B W McKendrick, who called our attention to this method of treatment of abortus fever

## Medical Memoranda

### Pneumococcal Meningitis in an Infant of 8 days Recovery

The value of intrathecal penicillin in pneumococcal meningitis is now established, but the optimum dosage still seems to be a matter for controversy Shalom (1945) reported eight cases of pneumococcal meningitis with three deaths, the patients having been given intrathecally 4 000 units of penicillin daily together with penicillin intramuscularly and full doses of sulphadiazine orally As purer preparations of penicillin have become available larger doses have been used Smith, Duthie, and Cairns (1946) reported 18 cases (with only one death, due to fat embolism) treated with varying amounts of intrathecal penicillin but they never gave more than 20 000 units in one injection though 16,000 units 12-hourly were given in a few cases They state that injections of 40 000 units or over may cause fits or gumming of the subarachnoid space At that time they were using a preparation of penicillin containing 500 to 700 units per mg

The following case is reported because of the extreme youth of the patient and because of the very large doses of penicillin which were given intrathecally without any ill effect

### CASE HISTORY

A male child aged 5 days was admitted on Jan 16, 1947 with his mother, who had lobar pneumonia, for breast feeding He was fully examined on admission The cord had separated and the stump was dry and clean He was slightly jaundiced and apparently had been so since he was 2 days old His heart and chest were normal and his spleen was not palpable There was no neck rigidity and his mouth and throat were healthy He weighed 6 lb (2.7 kg) According to the mother his weight at birth was 7 lb 4 oz (3.3 kg)

In spite of adequate amounts of milk for a child of his size and age he had lost weight On Jan 19 he passed one green relaxed stool and his temperature was 100° F (37.8° C) No physical signs were found and his jaundice had faded On Jan 20 the temperature was 102° F (38.9° C) He was not taking his feeds well, and there was slight neck rigidity, but no other signs A lumbar puncture was performed, and a turbid yellowish cerebrospinal fluid was obtained Penicillin, 30,000 units, was injected intrathecally The report on the cerebrospinal fluid was as follows Opalescent fluid, lymphocytes, 6 per cmm, polymorphs 82 per cmm, total protein insufficient fluid, globulin, ++, chlorides 700 mg per 100 ml fluid, Gram positive diplococci + + + +, culture, profuse growth of pneumococci, penicillin sensitive

He was also given 0.5 g of sulphadiazine followed by 0.25 g four-hourly for seven days, then 0.125 g six hourly for seven days (total 14.6 g) 30 000 units of penicillin daily intrathecally for eight days (total 240,000 units) 30 000 units of penicillin intramuscularly three hourly for 16 days (total 2,880,000 units) and subcutaneous salines to combat dehydration when he was not taking feeds well

After three days there was some clinical improvement—less neck rigidity—and he took his feeds better At the end of eight days the pyrexia had almost settled and the cerebrospinal fluid was nearly normal Intrathecal penicillin was discontinued Further recovery was uneventful Owing partly to the fact that she was herself, the mother's milk dwindled in amount, and the baby was gradually weaned on to a proprietary milk preparation He was discharged on Feb 7 when fit and gaining well, his weight being 7 lb 2½ oz (3.25 kg)

### DISCUSSION

It must be unusual for so young an infant to recover from pneumococcal meningitis As the child was already in hospital early diagnosis and treatment were possible

A preparation of pure white crystalline penicillin, containing 1,650 units per mg, which is much less irritating than the older impure preparations is now available Certain points are thought to be of importance in the avoidance of reactions to the injections and of the introduction of secondary invading organisms The penicillin used was prepared in separate doses of 30 000 units in 3 ml, each in a sealed ampoule, this prevents contamination of the penicillin solution The small volume of the dose is, I feel, important, as large quantities of fluid may raise the tension of the cerebrospinal fluid considerably, particularly in small infants I always aim how-

at removing an equivalent volume of cerebrospinal fluid plus 1 ml before the injection. This should of course obviate that danger.

I wish to thank Dr B A Young, medical superintendent, St. Alfere's Hospital, and Dr B Gottlieb, senior resident physician, for permission to publish this case, and the latter also for his help in preparing the paper.

### Therapeutic Scurvy

The following case is of interest in that it shows the importance of viewing the body requirements as a whole when placing any patient on a dietetic regime.

#### CASE REPORT

The patient, a married woman aged 42, with one son aged 16 alive and well, was admitted to hospital complaining of swelling of the left leg for four weeks, with bruising of two weeks' duration. Five weeks before admission she noticed that her teeth were tender and that her gums were swollen and bled easily. Several teeth were extracted without undue haemorrhage. A few days before admission she got a severe pain in the left thigh, with a "cramping" sensation in the calf and the foot. She was sent into hospital as a case of thrombophlebitis.

Vision was blurred, but there was no definite night blindness. On admission she noticed dryness of the skin. There were no pins-and-needles or paresthesia, no soreness of tongue, and no haematuria. She had had no serious illnesses, but since the age of 8 had been subject to attacks of migraine, which had become more frequent two years ago. She consulted her doctor, who diagnosed nervous dyspepsia and put her on a diet. This consisted of 2 pints (1.14 litres) of milk a day which was simmered for some while before being consumed. She also had three eggs a week, steamed fish, bread-and-butter and milk puddings but she had no vegetables or fruit of any kind. No drugs were taken except stomach powders.

On examination she was seen to be thin and pale, and her lower gums showed purple red proliferations between the teeth. In the upper jaw where the teeth had been extracted, there was no abnormality. Examination of the chest and abdomen revealed nothing abnormal. Blood pressure was 120/60. The left leg was markedly swollen with discoloration of the whole thigh, the appearance being like an extensive bruise. Both legs showed many small petechiae. A blood count showed haemoglobin, 58%; red cells, 2,800,000; white cells, 6,000, normal differential count. Blood ascorbic acid was 0.1 mg per 100 ml. Urinary excretion of ascorbic acid was 2.15 mg in 24 hours.

It was considered that minimal doses of vitamin C would be of value. She was put on an ascorbic acid free diet and given 15 mg of ascorbic acid daily. After three days she noticed improvement in her teeth and the left leg rapidly became more comfortable. Three days later objective improvement in the leg and gums could be seen. In four weeks there had been no further bleeding from the leg and there were only traces of the petechial haemorrhages on the fresh ones. After approximately three weeks the urinary excretion was 7.1 mg in 24 hours and the blood ascorbic acid was 0.25 mg per 100 ml. She was given 15 mg of ascorbic acid daily and discharged from hospital but it was noted that large doses of vitamin C did not produce any beneficial effect.

The patient has been followed up since discharge. She still complains of dyspepsia but the haemorrhages have disappeared and on examination she has no symptoms.

#### COMMENT

This case of scurvy due to grossly deficient diet and emphasizes the importance of giving adequate attention to the diet used for treating dyspepsia. The diet was boiled. The very small amount of ascorbic acid required to cure the condition is also demonstrated. The minimum daily requirement of ascorbic acid is generally accepted as being in the region of 10 mg. It was observed that a dose as low as 15 mg was sufficient to bring about a cessation of bleeding from the gums and the condition was cured.

The patient was seen by Dr. J. P. P. at St. Alfere's Hospital, Greenwich, and Dr. J. P. P. at St. Alfere's Hospital, Greenwich. Dr. J. P. P. is a Medical Officer, M.D., M.R.C.P.

### Facial Seborrhoea in Arteriosclerotic Pseudobulbar Palsy

Profuse seborrhoea of the face associated with Parkinsonism is so characteristic of encephalitis lethargica that in exception to the rule is not without interest. In the following case the condition was due to arteriosclerotic degeneration of the brain.

#### CASE REPORT

The patient, a man aged 46, had never had seborrhoea until his present illness. Six months before admission his wife noticed that he seemed dull and sleepy, that he dribbled saliva, and that both hands were "shaky." He became slow in movement, irascible, and difficult to handle. His speech was slurred and his expression fixed.

On examination he looked older than his years, and his typically Parkinsonian face was thickly covered with a glistening film of sebum. The rest of the body was not so affected. He was given to fits of causeless weeping, but pathological laughter was not observed. He was disorientated for time and place, and showed defective memory for recent events. Insight and judgment were faulty, and he displayed a consistent disregard for cleanliness and the conventions. Speech was slow and slurred, it was embarrassed by Cheyne-Stokes respiration. There was no gross defect of sight. The fundi showed marked arteriosclerosis. There was a supranuclear paralysis of conjugate upward movement of the eyes, lateral and downward movements being intact. The tongue was spastic and could barely be protruded. Marked spastic rigidity of both arms and both legs was present. The left arm and leg were weaker than the right, and there was a left extensor plantar response, the right plantar was flexor. There was a coarse tremor of the fingers of both hands but it was not typically Parkinsonian. Voluntary effort of one limb increased the rigidity of the opposite side of the body, consequently his incapacity was more pronounced when standing or attempting to walk than it was when lying down. He walked with a spastic shuffle and festination. There was no gross sensory loss, but his mental state precluded tests of the finer modalities. Sphincter control was intact.

The left ventricle was much enlarged. Blood pressure was 280/140. The urine contained a trace of albumin and a few hyaline casts. Blood urea was 60 mg per 100 ml. The spinal fluid was normal in all respects, and the Wassermann reaction was negative in both fluid and blood.

Eight months after the first appearance of symptoms he had a series of epileptiform convulsions between which he remained in an attitude of decerebrate rigidity. Twenty-four hours later he died.

The post mortem report (Dr J. G. Cummings) on the findings in the brain was as follows. A recent haemorrhage filled the left hemisphere. Colloidin sections were cut from various parts of the brain and stained with haematoxylin, van Gieson, P.A.H. da Faria, and by the Gross method. Weigert-Pal preparations were also made. There is a widespread vascular abnormality with marked proliferation of the intima and endarteritis. Atheromatous patches are present. The most marked damage is in the midbrain and pons, where in addition to vascular changes there are small zones of demyelination in relation to the vessels. The cerebellum shows slight changes of a similar type and also some loss of Purkinje cells. Very few zones of cellular infiltration are to be seen, but in a few cases in the midbrain and pons there is some perivascular lymphocytic infiltration in relation to damaged capillaries. The appearances are those of arteriosclerosis; there is no evidence of encephalitis.

#### COMMENT

This case is of interest in two respects. First, it illustrates the sound rule that encephalitis lethargica should not be diagnosed except during an epidemic of that disease. Sporadic cases resembling it almost invariably turn out to be some other condition. Secondly, facial seborrhoea has not hitherto been described in pseudobulbar palsy. Its occurrence in this case is perhaps explained by the unusually rapid onset of facial rigidity, which in encephalitis lethargica, came on within a few weeks, in contrast to the usual insidious onset in arteriopathic Parkinsonism. The seborrhoea is limited to the face, and it is only in the face that rigid muscles by their insertion into the skin can impose immobility on the integument in which the sebaceous glands lie. It is suggested that the seborrhoea which occurs as a temporary phenomenon with rapidly developing Parkinsonian rigidity of the face has a mechanical explanation and is not due to a central autonomic disturbance. This view is in harmony with the current belief that the sebaceous glands are not under nervous control.

## Reviews

### MARXIST GENETICS

*Soviet Biology The Situation in the Science of Biology*  
Address delivered by Academician T D Lysenko at a session  
of the All Union Lenin Academy of Agricultural Science,  
July 31 to Aug 7 1948 Translated for Science Section  
of the Society for Cultural Relations with the U S S R (Pp 51  
2s 6d) London Birch Books

This address to the Lenin Academy by its president deals with the new epoch which he has created for science in the Soviet world. It consists in the first six sections of a philosophical-historical-social-political examination of the fallacies the jargon, and the reactionary pseudo science of the followers in Western countries and in Soviet lands of Mendel, Morgan, and Weismann. Lysenko shows in simple words how the great Darwin himself introduced a fatal error into his system by studying the 'preposterous reactionary ideas' of Dr Malthus. All these people have been led away from the true path of materialism, which was laid down, it seems, by Lamarck. They have been led either into 'feeble Morganistic metaphysics' or into mere idealism culminating in Schrodinger's book *What is Life?* which a Russian geneticist was so unwise as to translate last year into the language of Lysenko.

The next three sections demonstrate the practical value of the teaching of the great Russian plant-breeder Michurin. The evidence is again primarily philosophical. 'The organism and the conditions required for its life are an inseparable unity,' declares Lysenko. Is it possible perhaps under the Soviet rule to ignore that death (or even imprisonment) separates them? Such mighty truths are interspersed with general statements of achievements, reiterated from Lysenko's tract on 'Heredity and its Variability' (translated in 1946 by Dobzhansky), and of theories resting on long-discredited evidence of the inheritance of acquired characters.

These are the foundations of Soviet Darwinism, or, as it is now called, 'Michurinism'. The tedium of this recital was relieved, however, by the introduction of a new figure in Soviet mythology—always an interesting event. This was a certain Williams, even more obscure than Michurin, who unknown (but no doubt persecuted in his own country) helped the master to create the new science. We shall all watch Williams.

Now, however, comes the first sensational new fact, the announcement that with wheat 'after two, three, or four years of autumn planting (required to turn a spring into a winter crop) durum becomes *vulgare* that is to say, one species is converted into another'—one, incidentally, with a different number of those idealistic metaphysical bodies the chromosomes.

After this the feeling of the meeting must have become obvious, even to the speaker, for after a couple of references to Lenin and Stalin, Lysenko continues:

'Before I pass on to my concluding remarks I consider it my duty to make the following statement. The question is asked in one of the notes handed to me, What is the attitude of the Central Committee of the Party to my Report? I answer, the Central Committee of the Party examined my report and approved it.'

Lysenko then summarized once or twice again what he had said before, and concluded, 'Long live the Party of Lenin and Stalin'. The Academy endorsed his opinions. On Aug 26 the leading geneticists (the remnants of those liquidated in 1941) were dismissed from their posts. The Academy itself, the universities, and research stations were ordered to be cleansed, and books conveying Western scientific notions were banned in all educational establishments. Rarely has so small a work produced such great effects.

One footnote may be allowed. Lysenko did not say what deletions the Central Committee of the Communist Party had made before approving his report. One such deletion will be obvious to Lysenko's admirers abroad. There is no reference to last year's uncensored revelation—the notion that there is no competition within species. Some expert in the Central Committee must have noticed that this discovery was slightly at variance with the Marxist theory of the class struggle. The Western professors who have been sweating and tying

themselves in knots in imitation of Lysenko's contortions are thus caught in the middle of the act with their eyes shut and not knowing whether to go on coiling or to turn over backwards. It seems indeed to be as ungrateful a task playing at apology as at discovery under the Soviet circus master.

For the publication of this official work the English speaking world, and men of science in particular, are under a deep obligation to the anonymous translator and to that devoted body the Society for Cultural Relations with Soviet Russia.

### ADVANCES IN SURGERY

*Recent Advances in Surgery* By Harold C Edwards, C B C  
M S, F R C S Third edition (Pp 437, 131 illustrations 24s)  
London J and A Churchill 1948

This is a book which every surgeon should have. The author has recorded—and with an easy literary style—all the important contributions to surgery since the last edition was published. It is more than a digest of the literature, for he gives a balanced summing-up of all those surgical problems which are in process of being solved and about which divergent opinions are held. The chapters on abdominal surgery are particularly attractive, but what is the meaning on page 146 of the statement, "Fluid absorption is retarded but lymphatic absorption is increased"? This sentence needs elucidation. Mr R C Brock has written an excellent article on thoracic surgery. In discussing the treatment of heart wounds he has omitted all details of operative procedure except the method of approach, yet Harken could scarcely have obtained his extraordinary results without his simple technique for opening into the heart cavities and controlling haemorrhage. As no surgeon is likely to meet more than a very occasional case of heart wound he might naturally in his emergency turn to a book like this to refresh his memory of essential operative details: a book he would be more likely to have than the original papers. On the other hand the technical aspects of pneumonectomy are very thoroughly described.

Mr D W C Northfield's account of the nervous system is informative but we do not find quite such a clear summing up of neurological problems, perhaps because of the intrinsic difficulties of the subject. The statement that "if the craniovertebral axis [*sic*] be a rigid container, then in the erect posture the pressure in the ventricles and lumbar theca should be equal and should be the same in the horizontal as in the vertical position" is surely not right hydrostatically. This section however, is a very good review of neurological surgery for the general surgeon and will be particularly useful for those who are obliged to teach some of the more elementary facts to undergraduate students. Sir Stanford Cade in the section on radiotherapy crystallizes the modern outlook of the radio therapist in a very satisfying manner.

### MATERNITY NURSE

*De Lee's Obstetrics for Nurses* By M Edward Davis M D,  
and Mabel C Carmon R N Fourteenth edition (Pp 640  
illustrated 15s) Philadelphia and London W B Saunders  
Company 1947

The latest edition of this book is, like its predecessors based largely on the work at the world-famous Chicago Lying In Hospital. It is a grand book, but anyone expecting to find it a pupil-midwives' textbook of the type that we are accustomed to in Britain will be surprised. The difference is largely explained by the fact that in most areas in the U S A the counterpart of our midwife is the obstetric nurse, who does not ordinarily conduct deliveries on her own, she does not even carry out vaginal examinations except on the instructions of the medical practitioner. Only 2½ pages therefore out of more than 600 are on delivery by the nurse—and that merely when the doctor does not arrive in time. The authors' intention which they successfully achieve, is to supply the nurse with as much knowledge of normal and abnormal obstetrics, including operative and anaesthetic technique as is necessary to enable her to give competent and intelligent assistance to the doctor. References to the history of midwifery and to famous obstetricians of the past broaden the outlook of the reader and arouse interest. The authors describe in great detail the purely nursing

## NHS

No one expected that such a vast scheme as that outlined in the National Health Service Act of 1946 would begin in a way that would please everybody—least of all those upon whom the main burden of the work falls, the medical men and women of this country. The situation is still too confused to give anything like a clear picture of what is happening, but perhaps the most noteworthy fact is the eagerness with which the public has sought to take advantage of a service which, in effect, guarantees the supply, free of direct charge, of everything from wigs to iron lungs. There has been an overwhelming demand for spectacles and dentures, and a run on the chemist shops so fast at times as almost to exhaust the supplies of certain pharmaceutical products. Presumably in time the novelty will wear off and the demand for such things as spectacles will decrease as the numbers of those apparently needing them diminish. This rush of the public for remedies and appliances has put an acute strain upon the medical profession, especially those in general practice. Evidence comes in from all over the country that doctors' surgeries are crowded out, and the doctors themselves deplore that this heavy pressure of work has made it at times impossible for them to give their patients adequate care and attention. If the demand for the doctor's time continues at the present level we can foresee that in the event of an epidemic in the winter the life of the general practitioner in particular will become intolerable. The fact that there has been this huge demand for remedies, appliances, and medical advice may, indeed, be held to indicate that the economic consequences of ill health discouraged many from seeking assistance before July of this year, although the Minister of Health himself has felt obliged to urge the public to use the new Service with prudence and discretion. It would seem that the idea of getting something apparently for nothing has led some members of the public cheerfully to act in an irresponsible way and to disregard the cost which the country as a whole will eventually have to meet. For the first three months of the Service the national bill for eye-testing and spectacles was £981,951, for drugs, £1,905,447 and for dentists (including dentures), £1,232,057. These figures do not include the cost of treatment and appliances provided through the hospital service.

If medical men and women are to continue to give of their best the country at large must act in a more responsible manner and not create circumstances which will exhaust the profession and incidentally discourage those who may be contemplating taking up Medicine as a career. Although no exact figures can yet be given, it seems that a large proportion of those who might well have been expected to pay direct for their medical treatment have,

in fact, asked to be cared for under the National Health Service scheme. There has been a much sharper fall in private practice, specialist and general, than was expected by the profession. This is probably a reflection of the hard economic times in which we live, in conditions which fall with particular severity on the professional classes.

Our correspondence columns show that general practitioners from all parts of the country are critical of many aspects of the Service and are especially apprehensive about their economic position. It is not yet possible to assess the volume of discontent or to measure the extent of the economic distress. The Secretary of the B.M.A., in a letter to all practitioners (published in the *Supplement* of Oct. 23), gave a careful analysis of those factors which enter into the general practitioner's income, and recorded the fact that the total available income for general practitioners is now in the region of £45,000,000, as against £28,000,000 that was earned in 1938. In an industrial country such as Britain the majority of general practitioners will receive the greater part of their income from what were formerly described as "panel patients." So, given the numbers which any one doctor may have on his list, it would seem fair to assume that the general practitioner in the big industrial areas should be earning not less than he did before July of this year, but he is having to work very much harder for it, and in conditions which he deplores as unsuitable for the practice of good medicine. The position of general practitioners in rural and semi-rural areas is, however, different, although it will not be possible accurately to assess their economic position until mileage and special inducement moneys have been paid out. Topographical factors alone make it quite impossible for doctors in this type of practice to secure an equivalent income if all those in their district decide to take advantage of the National Health Service. The economic position of medical men and women in such areas is causing concern, and is a matter which the B.M.A. is taking up with a full sense of the urgency of the problem. It is imperative that men in established practices with families to educate and all the other numerous commitments which a doctor has to enter into should not suffer, and we believe, too, that public opinion fully informed of the situation would forcibly assert itself against economic injustice even though this may have been endured by a relatively small percentage of practising doctors. The Remuneration Subcommittee of the Insurance Acts Committee had before it on Oct. 28 an amount of evidence on which it is to assert the economic case of the medical profession. This can be asserted with all the more force in that the medical profession in May of this year decided to do its best to make the National Health Service a success. This it has done at the cost of much time and labour, and the country's sense of fair play, we may be sure, will be behind the medical profession's attempt to secure equitable treatment.

Among the points that have come out in our correspondence columns are the proposals that the capitation fee should be increased and fixed, that separate funds should be established for mileage and basic salary, and that there should be a reduction in the numbers of persons any one practitioner should have on his list. Another point is that

the maximum of £400 000 for special inducement payments should be reconsidered. It is well to recall that the Government gave general approval to the Spens Report on the Remuneration of General Practitioners. In terms of the 1939 value of money, it may be remembered the Spens Report recommended that between the ages of 40 and 50 approximately 50% of general practitioners should receive net incomes of £1 300 a year or over, that 75% should receive net incomes over £1,000 a year, that approximately 25% should receive net incomes of £1,600, that less than 10% should receive a net income of £2,000, and that it should be possible for a small proportion to receive net incomes of at least £2 500. These figures, it may be emphasized are *net* figures and in terms of the 1939 value of money. The medical profession is at the moment doing its job in extremely difficult circumstances, and it is up to the Government to meet promptly the causes of discontent which now prevail.

## FACTORS IN INFERTILITY

In a paper<sup>1</sup> published in this *Journal* in 1946 on the subject of the receptivity of cervical mucus to spermatozoa Dr Mary Barton and Dr B P Wiesner continued their combined clinical and biological studies of infertility. They then put forward the view that cervical hostility may be due to various factors including general debility, oestrogen deficiency, and local infection. Further work on these particular factors and their interrelations is reported by Drs Barton and Wiesner in the opening pages of this issue. The authors selected infertile women aged between 30 and 40 in whom the main cause of infertility was considered to be hostility of infected cervical mucus to spermatozoa. The infecting organisms were predominantly of intestinal type, and the women were all more than 10% heavier than the mean weight for their age and height. After excluding those women in whom the cervical mucus regained normal receptivity after treatment with oestrogens, antibiotics, and local applications 88 remained to form the subjects of the investigation.

In the first 14 cases the resistant cervical infection was treated by means of a sucrose free diet, supplemented by vitamins with the object of encouraging the growth of a healthy intestinal flora. The authors have not included reports of the results of subsequent bacteriological examination, and there is no mention of whether their objective was attained. In nine of the 14 cases, however, the cervical mucus became normal mostly after resumption of treatment for the infection in addition to the special diet. It was concluded at this stage however that the response to treatment was better in those patients who lost weight on the diet than in the remainder of the women were not treated. Results of the same order were obtained in the next 22 of the 88 cases the cervical mucus returned to normal in not less than 70 cases conception followed. The percentage of successful results was more than 50% in the patients who lost weight than in the remainder. It has often been noted that some of the conditions which are associated with infertility, such as obesity, are also associated with endocrine disturbance.

which also includes impairment of gonadal function. Many workers have reported that reduction in weight, usually brought about by a diet of lower calorific value and by the administration of thyroid, can increase fertility. Barton and Wiesner attempted to exclude this type of case by requiring evidence of the regular occurrence of ovulation, and they maintain that reduction in weight brought about by a sucrose-free diet of high calorific value helps to restore the normal cervical function though how it does so is not clear.

A relation between nutrition and reproductive efficiency exists in some animals, but the results of animal experiments have not always been applied scientifically to human beings. One of the best examples of this concerns vitamin E, which has been used extensively in the hope of improving the fertility of both man and woman. It now seems generally agreed that it has little if any value, and this was the consensus at the recent annual conference held by the Family Planning Association in Exeter<sup>2</sup>. This is not surprising when it is remembered that the original experiments on which the treatment was founded showed that vitamin-E deprivation causes abortion but not infertility in female rats<sup>3</sup> and in the male leads to testicular degeneration which is irreversible<sup>4</sup>.

It is always difficult to assess the importance of any one infertility factor, and this is particularly true of conditions such as obesity and cervical hostility. Thus it was often noted, at all events before the war, that some women in the poorest section of the population living mainly on starchy foods were both remarkably obese and fertile. Again although much has been written on the importance of the mucous barrier in the cervix, it seems wise to retain a healthy scepticism. There is still disagreement among workers in this field, and the importance of the quality and quantity of mucus in an apparently healthy cervix has never been convincingly established. Pregnancy, in fact, frequently occurs despite the presence of obvious cervical infection, and Barton and Wiesner admit that a spontaneous restoration of normal cervical function occurred in one of nine untreated cases within six months.

Although the state of the cervical canal almost certainly affects fertility, there may have been a tendency in recent years to exaggerate its importance, sometimes to the neglect of what might be termed fundamental investigations. A carefully taken personal and marital history of the infertile couple together with general and local examination of them both will often indicate the fault or at least give a guide to it. In a large percentage of the remaining cases the probable cause will be discovered from the results of investigations which are now almost routine. First, thorough and repeated analyses of a complete specimen of semen should be undertaken. Semen removed from the vagina after coitus is unsatisfactory for this purpose. In the woman tests for ovulation are carried out and also

endometrial biopsy (which sometimes reveals an unsuspected tuberculous infection) Insufflation of the tubes is not a completely reliable guide to tubal patency and should be supplemented by hysterosalpingography with screening, and again the result of one test is not conclusive. Moreover, even when the tubes are patent careful study of hysterosalpingographs may reveal adhesions interfering with the passage of the ovum from the ovary to the abdominal ostium. Post-coital and *in vitro* tests of cervical mucus with a view to determining its receptivity to spermatozoa are supplementary to the above, and for practical purposes are really necessary only when the cause still remains in doubt and when dilatation of the cervix and the passage of gas or other medium have failed to have a therapeutic effect.

But what of the cases in which all the tests are negative and no cause is found? Mr Christie Brown, whose paper also appears in this issue of the *Journal*, points out that sometimes childlessness may result not from the failure of fecundation but from the inability of the fertilized ovum to embed itself successfully in an endometrium not fully secretory in type. He treated a number of patients on this assumption—for it is not proved—with 0.6 mg 'dien-oestrol' and 10 mg 'ethisterone' daily from the expected date of ovulation to the beginning of the next period or, if conception occurred, until the 18th week of pregnancy. This dose of ethisterone might almost be called homoeopathic when it is remembered that it is probably equivalent to only about 1.5 mg of progesterone by injection, yet he reports that at least 38 out of 111 patients became pregnant within six months of starting this treatment. The results of any treatment for infertility are not easy to assess, and it is rarely justifiable to claim a cure. Mr Christie Brown also reports good results with his regime in cases of habitual abortion, another condition in which it is difficult to relate treatment and outcome. Apparent success in such cases has been reported by others who employed much larger doses of oestrogen and progesterone<sup>5</sup> or of progesterone alone.<sup>6</sup> Among the latter MacGregor and Stewart<sup>8</sup> dryly comment that "there is almost an air of the miraculous about the results reported on doses which are almost infinitesimal in comparison with the amount of progesterone produced in normal pregnancy". It should be noted, too, that an almost equal measure of success is claimed for other therapeutic agents, including thyroid, vitamin E, blood serum, and even cold baths. Workers in this field should always keep in mind the findings of Malpas<sup>9</sup> on the spontaneous cure rate to be expected in cases of repeated abortion.

The subjects of sterility and abortion bristle with difficulties when it comes to the appraisal of probable causes and the results of treatment. There has been so much loose and inaccurate thinking and writing in this field that Swyer has recently found it necessary to present a paper criticizing some of the papers on infertility which have been published during the last two years. If a scientific outlook is essential for the advancement of knowledge a proper perspective is important in the interests of the patients. Over-zealous and misguided inquiry and treatment can convert a complaint into an obsession, to the detriment of health and marital happiness.

## PRESIDENT TRUMAN AND MEDICINE IN THE U.S.A.

With Mr Truman as President, and with a Democratic majority both in the Senate and in the House of Representatives, it looks as if the Federal Government will go ahead with plans which have been described by Senator Taft as "a socialistic monstrosity". Early this year Mr Truman asked Mr Oscar R. Ewing, the Federal Security Administrator, to undertake "a comprehensive study of the possibilities for raising health levels and to report upon feasible goals which might be realized by the American people in the next decade". Mr Ewing presented his report, a summary of which appears on page 869, to the President on Sept. 2, but it is doubtful if anyone except the President himself believed that the recommendations made in the report would ever be matters of practical politics. The whole outlook has now changed, and the coming struggle between the Government planners and those who abhor all their works promises some bright displays of fireworks.

Few Americans would to-day disagree that their medical services could not be greatly improved, it is the method of making improvements which provokes controversy. In a comprehensive survey of the American medical services Professor T. McKeown<sup>1</sup> points out that at least 25% of the counties are without basic public health services, 40% have no registered hospitals, doctors are very unevenly distributed, and the costs of medical care are quite beyond the means of many people who are either not protected or are inadequately protected by voluntary insurance. The need for more hospital beds led to the passing in 1946 of the Hospital Survey and Construction Act. This law requires States to submit plans to the Surgeon-General for a complete hospital service based on comprehensive surveys, and the regulations set forth standards for the number of beds to be provided in various categories. This Act was conceived in the House of Delegates of the American Medical Association, and it was supported by all sections of medical and political opinion mainly because the hospitals are to be developed under State and not under Federal control and because provision is made for hospital buildings but not for the staff required to operate them. Professor McKeown remarks in his paper that American experience is no exception to the general rule that fundamental changes in the organization of medical services seldom occur without widespread political controversy. In the Senate hearings on the Murray-Wagner-Dingell Bill (for a prepayment medical service similar to our own N.H.I.) official expressions of opinion were presented by organized labour, the American Association of Manufacturers, the Chamber of Commerce, the Farmers' Union, the National Lawyers' Guild, the League of Women Shoppers, and many other organizations. Apart from the opposition of the American Medical Association, the States of the Union have no wish to see the Federal Government intrude on local affairs, and at present health is certainly included among such affairs. The Federal Security Agency, which is responsible for the Federal

<sup>1</sup> *Brit. J. Soc. Med.* July 1948. In the press.

<sup>2</sup> *British Medical Journal* 1948 1 645.

health services as well as education and social welfare, is not a cabinet department, though there is a Bill now under discussion to provide for the establishment of a cabinet department of health, education, and security.

In preparing his report Mr Ewing consulted many persons inside and outside the Government, and in particular has been guided by the findings of the 800 persons who met in the National Health Assembly in Washington in May of this year. The Medical Care Section of this Assembly unanimously agreed that "the principle of contributory health insurance should be the basic method of financing medical care for the large majority of the American people." Mr Ewing points out that there was disagreement on how such insurance should be effected, but he finds himself compelled to recommend a scheme of national health insurance. This is likely to give rise to considerable controversy and to be opposed by the American Medical Association. It may be recalled, too, that in the series of investigations conducted by the New York Academy of Medicine and reviewed in these columns<sup>2</sup> the conclusion was reached that health insurance should be conducted on a voluntary basis. In Mr Ewing's view a satisfactory system of health insurance should provide "(1) That everyone should have ready access to adequate health and medical services, (2) that everyone should have the kind of services, and all the services, he needs to promote better health, and (3) that everyone should be able to obtain these without regard for the level of his personal income." These criteria, he observes, go beyond any voluntary insurance plan. He considers that only about half the families in the U.S.A. can afford on a voluntary basis even a moderately comprehensive health insurance plan. He provides arguments against the six principal objections to a Government health insurance, namely "(1) That Government health insurance is socialized or State medicine, (2) that it is compulsory, (3) that it would be highly centralized and would concentrate too much power in Federal Government, (4) that there are not sufficient personnel and facilities to make it effective, (5) that it would cost too much, and (6) that it would open the way to over-use and other abuses and would lower the quality of medical services." Socialized or State medicine, Mr Ewing observes, means that the Government owns and operates all hospitals, and that practising physicians are employed by the Government on a salary basis, but this is not the plan laid down in his report. There would be full freedom to doctors, hospitals, and other health agencies in deciding whether they would participate in the scheme, and the method and rate of payment would be matters for negotiation. Compulsion to contribute would be no innovation, because payments for unemployment and old age insurance are compulsory. "The benefits of these systems are well established, and they are an accepted and valuable part of our American way of living." The administration of the plan would rest mainly with the States, and the part of the Federal Government would be to aid the State programmes and "to handle the finances of the total system." As to shortage of personnel and facilities, this is recognized, but Mr Ewing considers that his plan will provide for the increase of medical manpower and facilities. He considers that the cost of running a national

health insurance scheme would be less than the expenses involved in the voluntary non-profit plans. He examines carefully the charge that a system of Government health insurance "would inevitably lower the quality of medical service." In the pattern of legislation recommended in his report Mr Ewing is confident that the insurance system "should be fully insulated from 'politics' of all sorts, so that purely medical concerns are left in the hands of the physicians and there is no unwarranted interference or 'political control of medicine'." The views of the Republican Party were summed up by Senator Taft in these words: "We have adopted in this country as a supplement to the private system the principle that the Government will supply through the State a minimum standard of subsistence, of housing, of medical care, and of education for every citizen. The minimum standard cannot be so high as to destroy the interest of men in securing something better through their own efforts."

Assistance in providing medical care should be confined to the group unable to pay for doctors' services so that there be no socialized medicine. Initiative and administration should rest on the local and State authorities."

We may therefore expect to see medicine the centre of a lively political struggle in Congress, with President Truman using the great personal victory he has gained to enforce Mr Ewing's plan. The medical profession in this country will watch with interest and sympathy the way in which the American medical profession will meet a situation which a few weeks ago the assessors of public opinion in the U.S.A. suggested would be postponed for at least another four years.

### ORAL PENICILLIN IN CHILDREN

An important question in connexion with penicillin treatment is the extent to which oral administration is justifiable. Against the single advantage of convenience must be set its extravagance, the dose required being at least five times greater than that injected, and the grave disadvantage of marked irregularity of absorption. All observers who have carefully studied its effects have noted that absorption varied widely from case to case, with the result that in any series of patients some will inevitably absorb only inadequate quantities of a dose which will suffice for others. The general adoption of the oral route also opens wide possibilities of misuse, particularly the self-treatment of venereal disease. Giving penicillin by mouth to infants and children, however, is a rather different matter: they are naturally less tolerant of injection and require oral doses on a less extravagant scale. Two years ago Buchanan<sup>1</sup> suggested that infants under six months should absorb penicillin better than older children and adults because of the low HCl content of their gastric juice, and her own observations on 25 babies supported this. Satisfactory blood levels were obtained by adding penicillin to feeds in amounts equivalent to a daily dose of only 4,000 units per lb (454 g) of body weight.

Various authors, including Suchett-Kaye and Latter<sup>2</sup> in this *Journal*, have reported favourably on the treatment of acute infections in young children with oral penicillin. Two publications on this subject, both from the U.S.A., tend rather to emphasize the limitations of the method

<sup>1</sup> *Lancet* 1946 2 560

<sup>2</sup> *British Medical Journal* 1947, 2 953

<sup>3</sup> *Amer J Dis Child*, 1947, 74 19

<sup>4</sup> *J Pediatr* 1947 31 195

than to reclaim its efficiency. Reisman and his colleagues<sup>3</sup> begin with the disquieting statement that 'several children have been admitted to the wards of the Queen's General Hospital with advanced pyogenic diseases of various types after ineffective oral treatment with penicillin at home'. They add that such treatment frequently makes the causative organism more resistant, but the implication that resistance has been acquired *in vivo* would have to be confirmed. They themselves treated 22 children, most of whom had upper respiratory tract infections, with large doses of oral penicillin, from 50,000–1,000,000 units being given every hour by day and every two hours by night. The results were 'fair' in 12 patients, in the remaining 10 there was no apparent effect. In the majority no penicillin was detected in the blood, which is surprising in view of the amounts given, but this may perhaps be explained by irregular administration: case 4, for instance, receiving "1,000,000 units every hour while awake and every two hours while asleep" for five days, is stated to have had a total dose of only 7,800,000 units—an unexplained discrepancy. The patients' ages are not stated, and there are no bacteriological data. Possibly some of the infections may have been caused by insusceptible organisms. The more valuable part of this paper is a study of absorption after oral administration, this again emphasizes what many previous authors have observed—namely, the importance of an empty stomach if absorption is to be adequate. Buffers and tablets were found to have no advantages, a simple solution in water being recommended.

A similar study was made by Markowitz and Kuttner.<sup>4</sup> They gave a standard oral dose of 50,000 units to children at various times before and after meals, and found that a satisfactory blood level was usually maintained for two hours only when the dose was given after a 4-hour fast. According to these findings the continuous maintenance of a therapeutic blood level by the oral administration of any reasonable dose must be impossible. It may well be concluded that older children should be treated like adults and given penicillin intramuscularly, at least in the first stage of the treatment of any severe infection. The form of oral treatment with penicillin which has the best justification is the addition of the drug to the feeds of infants in the way suggested by Buchanan.

### SAFER MILK TO COME

Once more, this time by Dr Wyndham Lloyd in a recent Chadwick lecture which is reported on another page, the attention of the country has been drawn to the tragic fact that in England and Wales each year just under 2,000 people die of bovine tuberculosis. This takes no account of morbidity—the number of persons who need treatment must amount to several thousands—nor of the waste of time, money, and hospital facilities that the treatment of this large number of patients must involve. These deaths and this waste are preventable. The infection is caused by drinking milk drawn from the udder of a cow which is suffering from tuberculosis. In a letter appearing in *The Times* of Oct. 30 Lord Bledisloe has pointed out that Great Britain, with about 40% of her cattle infected with tuberculosis, is at the bottom of the list for Western Europe, while in the USA and in Canada the figures are 0.5% and 2% respectively. The Danish agricultural attaché has stated that in 1947 in his country 97.4% of the cattle were healthy. It should surely be possible to improve upon our own deplorable figure.

But an improvement in the health of our dairy herds is not enough. There is an urgent need for much more pasteurization of raw milk. About one quarter of the milk supplied to schools is neither from a T.T. herd nor has

it been pasteurized, and this is given by local education authorities to children when they are at an age highly susceptible to bovine tuberculosis. There is no danger in pasteurization, and the process has the additional positive advantage that it destroys organisms of the *Salmonella* and other groups. The amount of vitamin C in milk—the destruction of which is used as an argument by those who oppose pasteurization—is small. There are, however, objections to relying upon only one method of making milk safe for the consumer. Tuberculin-tested milk has come originally from a healthy cow, but infecting organisms can easily gain access to milk between the cow and the consumer while pasteurized milk may become reinfected after pasteurization—to the great detriment of children under the age of 2 years. Further, the installation of pasteurizing plant in rural areas is impracticable. The building-up of healthy herds must therefore be encouraged while at the same time much more milk is pasteurized than hitherto. In his speech at the opening of Parliament His Majesty said that proposals would be laid before the Houses "to provide for a safer milk," and it is to be hoped that these proposals will concern both the Ministry of Health and the Ministry of Agriculture, in this way the promise given by the Government to Lord Rothschild, when he raised the question in the House of Lords in April 1946 will be fulfilled.

### CEREBRAL ABSCESS AND CONGENITAL HEART DISEASE

Although cerebral abscess has been recognized as a complication of congenital heart disease for at least 68 years—Ballet<sup>1</sup> described it in 1880—it is not generally known that it is the cause of death in about 5% of all cases. Gates Rogers, and Edwards<sup>2</sup> have recently reported five fatal cases from the Mayo Clinic. Fallot's tetralogy, which is the underlying lesion found in 50% of recorded cases, was present in two of these, but two others had nothing more than an atrial septal defect. Bacterial endocarditis was absent in all. The authors point out that the abscess is commonly solitary and may be amenable to surgical treatment. There can be little doubt that the cause of the abscess is paradoxical infected embolism, and therefore it occurs only with permanent, transient, or intermittent veno-arterial shunts. It has been seen in association with an arterio-venous aneurysm of the lung. Although cerebral abscess has not yet been reported following cardiac catheterization in this country, the procedure should be undertaken with special care in patients with congenital heart disease who are known to have a right-to-left shunt. It is never safe to clear a blocked catheter by means of pressure from a syringe, the catheter must always be changed. To prevent accidents a suitable dose of heparin should be injected at the start (50 mg. for an adult, about 25 mg. for a child of 8–12), and 100,000 units of penicillin three times daily, should be given during the subsequent 48 hours.

Dr J. A. Charles, F.R.C.P., will deliver the Bradshaw Lecture on "Victorian Medical Administrators and Their Significance for To-day" before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday Nov. 23, at 5 p.m.

The next session of the General Medical Council will open on Tuesday, Nov. 23, at 2 p.m., when the President, Sir Herbert Lightfoot Eason, will take the chair and deliver an address.

## MEDICINE IN THE U S A

### REPORT TO MR. TRUMAN

At the beginning of the year President Truman requested Mr Oscar R Ewing, Federal Security Administrator, to "undertake a comprehensive study of the possibilities for raising health levels and to report upon feasible goals which might be realized by the American people in the next decade." The report, entitled 'The Nation's Health,' has now been published, and amongst its main recommendations are the training of more doctors, dentists, and nurses, the building of more hospitals, compulsory health insurance for all employed persons and their dependants, improved care for children and the chronic sick, the rehabilitation of the physically and mentally handicapped, and the local integration of all the health services.

#### The Need for Doctors

In order to estimate the total number of doctors required, Mr Ewing has chosen as an approximate indication of the proper standard the present average figures for the top twelve of the 48 States. This works out at 667 people for each doctor. Such an increase of doctors even at the end of ten years is admittedly impossible, and Mr Ewing sets as a goal for 1960 a net gain of 15 000 doctors, 5 000 dentists, and 17,500 nurses over the numbers which would be produced at currently expected rates. To obtain the 15,000 additional doctors Mr Ewing recommends that medical schools must be expanded, new ones built, and Federal scholarships awarded to needy students. Perhaps it is significant of the U S A that he estimates that the output both of trained psychiatrists and of paediatricians needs to be three times the present rate. A lowering of existing barriers against negroes entering State and private medical schools would assist in overcoming the deficiency.

From the conclusion that medical schools can be expanded by no other means than by using public funds the report recommends that \$40 million a year in Federal funds should be made available as a beginning only for salaries, equipment, and construction. The question of Federal medical scholarships is more complicated, since this constituted a major part of the recommendations of the very able professional President's Committee on Higher Education of 1947 but it is emphasized that in planning medical scholarships with Federal funds care should be taken that medical schools, through taking students later than other professions, would not be cheated of the most promising scholars.

#### Hospital Beds

The lack of hospital beds is even greater, largely because of the uneven distribution of the national wealth between the States. And it is the States, primarily, which must take the initiative in building up the hospital service. At present almost three quarters of general hospital beds in the U S A are operated by non-profit voluntary organizations, even in the boom year of 1946 their average annual deficit ran to 13% of total costs. The national goal is taken from basic standards set by the States themselves under the Hospital Construction Act of 1946. This sets a basic standard per 1,000 population of 4.5 general hospital beds, 2 beds for the chronically ill, 5 beds for mental patients, and 2.5 sanatorium beds—a round total of 14 beds per 1 000 people. By this standard the United States, with 900 000 'acceptable' hospital beds, has less than half the hospital capacity it really needs.

At present the Hospital Construction Act adds one Federal dollar for every two raised from State and local resources. In most States no laws have yet been passed to meet the Federal offer. According to the report, "Many areas of the country cannot finance new hospitals either because they cannot contribute enough towards construction or because even if hospitals were built the local income levels are so low that sufficient income for hospital operation and maintenance cannot be guaranteed. Indeed, 40% of American counties have no general hospitals at all. From this analysis Mr Ewing concludes that the Federal Government must not only assist in building new hospitals but will have to subsidize the

maintenance costs of voluntary hospitals. Even by doubling present budgets the further 900,000 beds needed could not be constructed in under 15 years. The Federal share of costs, moreover, should be raised from a third to 40% for construction, and in special low-income areas also to 40% for maintenance—the States providing another 40%.

#### Health Insurance

At the combined lay and professional National Health Assembly held in Washington this spring the Medical Care Section could agree only that "the principle of contributory health insurance should be the basic method of financing medical care for the large majority of the American people, [and] should be accompanied by the use of such tax resources as may be necessary to provide additional services for special groups and services not covered by prepayment or insurance." But it admitted a deep division between the American Medical Association and many of the lay delegates from national social and labour organizations regarding whether a National Health Insurance plan was necessary to achieve this end. Mr Ewing concludes that compulsory national health insurance is necessary. According to his report voluntary prepayment plans do not generally provide for hospital services for more than a limited period or for mental, venereal, or tuberculous patients. Voluntary plans offering physicians' services fail to provide in general for care outside the hospital. But the chief objection against them is at bottom a financial one—either services offered must remain incomplete or the costs must be raised, with the result that only the affluent will be able to afford the contributions. Present charges for prepayment plans in the U S A range from £12 to £18 a year. According to the report this already excludes all the 18 million Americans dependent on incomes of less than £250 a year, most of the families with £250–500 a year, and about 70% of the £500–750 a year group. The net result already is to rule out the lower half of American families.

#### Scheme for Employees and Dependants

The fact that by these plans, in or out of the Blue Cross organization, a flat rate is charged irrespective of income has plainly influenced Mr Ewing to suggest that contributions for national health insurance should be based on a percentage of the employee's wages. Learning perhaps from British difficulties, he advises a three-year "tooling up" period after the necessary legislation has been passed by Congress before any benefits under the scheme are made available. In this period procedures in each State and locality could be minutely worked out, machinery set up, and people thoroughly informed of what they were entitled to and under what conditions. Even then services under the insurance scheme would be related strictly to available resources. Later these resources could be expanded and improved until the full scheme was in operation.

No detailed limits are set in this report for the scope of the compulsory insurance beyond saying it should be as broad as possible and should cover dependants. It is insisted that legal guarantees should be given to insured persons of complete free choice of physician, dentist, or hospital, that all personal records should be confidentially kept, and that there be a right of appeal to proper committees and even courts against administrative decisions. The medical profession, on the other hand, would also receive legal guarantees that participation in the scheme would be by free choice, that their right would be protected to accept or reject individual patients, to retain control of professional aspects of professional service, to choose the method of payment, to negotiate rates of payment through representatives of their own choice, and to have a corresponding right of appeal against administrative decisions. Administration of the scheme would be by a small board of full-time members, who would be both professional and lay. The board would be so constituted as to co-ordinate the insurance scheme with other social security and public health programmes. The members would be aided by a larger advisory council representing the interested public, the consumer, and professional groups. The details of administration could be designed to fit in with existing social security agencies.

The complete plan—at some unspecified date after 1952—would at least cater for those Americans already protected by social

security legislation for old age and other benefits—about 85 out of 140 millions—with in addition farmers and agricultural labourers at present excluded. Complete services of general practitioners and specialists would eventually be made available, though at first this would be difficult. Hospitals also would be open to insured persons though they would continue to be autonomously governed by their existing managers. Extra charges for private rooms and, at first for long stays would be necessary. With dental care, too full provision would at first be impossible, and it might have to be limited to children. Nursing services again might have to wait on long term improvement in some areas.

### Mental Health

Plans for improving mental health are also proposed. The report quotes some interesting figures to show prevalence of mental illness. Ten per cent of the men examined for military service during the last war were rejected for neuro psychiatric disorders. In addition to these nearly 500 000 developed mental ill health at a later date. The loss in military man-power from these causes totalled nearly 2 000 000. It is estimated that 8,000 000 persons in the U S are suffering from mental disease.

At the present time the nation has 4 500 psychiatrists, 5 500 nurses working in psychiatric hospitals, and 1,000 qualified psychiatric social workers. It is estimated that \$75,000 000 must be devoted to training-centres and grants for students in order to overcome these very serious shortages which are worst in the State mental hospitals. Chiefly through lack of space there is overcrowding in these hospitals ranging from 20 to 70% above accepted standards. They suffer from a 50% shortage of attendants and an 80% shortage of trained nurses. Public mental hospitals have one quarter of the number of psychiatrists needed. The present patient day cost is said to be only \$1.50. In addition to measures aimed at remedying these conditions the report advocates the increase of the existing 600 psychiatric clinics to a number which would provide one for every 100,000 persons.

### The Chronic Sick

Under the heading "Healthy Maturity" the report advocates increased research programmes in geriatrics and chronic disease. It estimates that 70% of sufferers from such diseases can be treated at home. To meet this an additional 50,000 public health and visiting nurses must be added to the present 21 500 in existence. Housekeeper services, group living, and foster-homes are also advocated. An additional quarter of a million hospital beds are recommended to supplement the 39 000 which are at present believed to be available for the chronic sick. Both specialized hospitals for chronic disease and chronic units in general hospitals are recommended.

Vocational rehabilitation is already attempted, but the scale is inadequate. Each year 9 000 persons are rehabilitated out of an annual requirement of a quarter of a million. The major share of this work still falls upon voluntary agencies. It is calculated that an increase of Federal appropriations from \$18 000 000 to \$70 000 000 and State appropriations from \$7,000 000 to \$30 000 000 would supply the nation with a complete rehabilitation service.

The remainder of the report deals with an extension of child health services at an estimated cost of \$430 000 000 a year and the development of local health units each staffed by one full-time medical health officer per unit, one additional full-time public health physician for each 50 000 population, one full-time nurse for each 2 000 to 5 000 population, one sanitarian for each 15 000 population, one health educator for each 50 000 population, and one clerical worker for each 15 000 population. For this purpose an initial appropriation of \$40,000,000 rising in five years to \$50 000 000 is suggested.

Finally Mr. Ewing discusses the broad framework within which these services would operate and the importance of integration between the medical centre, district and community hospitals and rural clinics. The report ends "If the people will get together—professional workers and public representatives alike—in citizen health councils throughout the country we will have the satisfaction of proving not only that health is everybody's business but that it is good business, essential business and successful business."

## PREVENTION OF TUBERCULOSIS ENVIRONMENTAL FACTORS

A Chadwick public lecture was given on Nov. 2 at the Westminster Hospital Medical School by Dr. WYNNDHAM E. B. LLOYD, tuberculosis officer for South Devon, on the subject of the prevention of tuberculosis with special reference to environment.

Dr. Lloyd said that tuberculosis was not a mere disease, it was a social and economic problem. It struck down alike the adolescent, the breadwinner, and the housewife. It was an infectious disease, the infection being of two types, human and bovine. Its prevention should be simple, but in fact it was a problem of extraordinary difficulty. Tuberculosis began insidiously, the sufferer remained infectious for very long periods and it was not acquired by one unlucky contact but, for the most part, after massive doses of infection over a long period. The incubation period was very variable, in some cases the first detectable signs of tuberculosis might develop years after the patient had been removed from a source of infection.

To prevent infection the first step was to discover which individuals already had the disease. It was necessary to examine not only the patients but all with whom they had been in direct contact. The examination had to be carried out from two points of view: the ascertainment of the source from which the patient might have acquired the infection, and the direction in which he might have imparted it. It was a fact that among contacts there was a larger proportion of people with tuberculosis than in the ordinary population. When cases were found they must be treated and educated so as to be no longer a danger to others.

### The Tuberculosis Service

To deal with this apparently simple problem a great tuberculosis service had grown up. It began with voluntary effort. In 1911 the National Health Insurance Service came into being and in 1912 the present scheme was launched, the purpose of which was to ensure that no sufferer should go undetected and untreated. Patients were sent to the tuberculosis officers by their own doctors, and the first step was diagnosis. Clinical bacteriological, and x-ray examinations were undertaken. Contacts were also called for examination. Mass miniature radio-graphy was now available.

The treatment of the patient was based on food, rest and fresh air, although more active measures, such as artificial pneumothorax, were adopted in suitable cases. If all these methods failed or the case was unsuitable for such treatment a chronic case remained with an infection which might exist for years. It was not practical politics to segregate these people permanently, and with proper instruction and reasonable living conditions they were not a danger to others. It was all a matter of good housing, cleanliness, and common sense.

Too much stress could not be laid upon environment in the prevention of tuberculosis but the word must be interpreted in the widest terms. It included adequate housing, water supply, proper ventilation, absence of overcrowding. Children must have sufficient diet to build up resistance, and there must be freedom from want, from fear, and from insecurity. Having put a patient in a sanatorium, it was no use sending him back to a overcrowded slum where he could not put into operation what he had been taught. Contacts must be examined and submitted to x-ray inspection every three months for at least two years. Every member of the household, young or middle aged must be examined. The main reservoir of infection was the sputum positive person who did not know or care. Tuberculosis was sometimes found in the middle aged person who had had bronchitis for years, and on looking into the family history it might be found that a baby had died of tuberculous meningitis, or an adolescent had died of the disease many years before and the parents had never been examined and were spreading infection undetected all the time. Many of these chronic carriers felt perfectly well if they had a cough it was put down to bronchitis or possibly to smoking. The problem of finding these carriers was acute, although mass radiography was of much assistance. Their numbers were great and segregation would not be practicable so that the obvious recourse was education. The patient must be taught how to dispose of sputum, the need for keeping separate from those of others his eating and drinking utensils and his personal linen must be impressed upon him and he must be instructed to avoid kissing and fondling

children These were common sense measures to be taught at sanatoria and by the staff of the tuberculosis officer, which should include health visitors, who would attend the clinics, particularly on older patients' days, so that they could get to know the people and their families. Personal contact was important, and it was as a friend of the family that the health visitor must appear in the home.

If housing accommodation was unsuitable, better accommodation should be asked for on behalf of such patients. Housing committees must be made aware of the fact that if tuberculous families were not provided with proper housing nothing would stay the disease. In country districts shelters might be set up in the garden so that the tuberculous person lived away from the other occupants of the house.

In a passing reference to bovine tuberculosis Dr Lloyd said that the methods of preventing spread due to drinking milk from infected herds ought to be simple to apply. All milk not taken from tuberculin-tested herds should be heat-treated and no one suffering from the disease should be allowed to handle the herds or the milk. Some schools still provided children with raw, untreated milk, and this should be remedied as soon as possible.

#### Present Position

At first sight the results of the work done in combating tuberculosis seemed very unsatisfactory. Infections were increasing, the total of known cases of the disease was greater, and waiting lists for sanatoria were very long. But the position was not quite as black as it might seem. More cases were known, but that was not to say that more existed. Notifications were no indication of the increase of the disease, for the more the research was intensified the greater the number of cases which would be found. The larger the number found the better would be the position from the standpoint of prevention, and it was not until all cases were discovered that it could be said positively that new cases were on the decrease. The most reliable guide was the number of deaths reported, although this also must be regarded with caution. Twenty years ago not nearly as many people with chronic coughs had x-ray examinations as was the case to-day, and the cause of death was often certified as bronchitis. Between 1914 and 1943 the crude death rate for pulmonary tuberculosis had been reduced by more than 50%, but the figure for 1943—the year with which the most recent report of the Registrar-General was concerned—was not so good as the figure for 1942.

The scheme which had been taken over by the regional boards under the new Act was to be reviewed by March, 1949. It was to be hoped that all available resources would be mustered for an intensification of the methods of treatment and prevention. More doctors, more radiographers, and increased nursing staff in hospitals and sanatoria were needed. Many beds were empty because of lack of staff. More mass radiography units should be available. But what was most needed, said Dr Lloyd in conclusion, was public enlightenment. Large numbers of the public did not realize how important it was that they should co-operate with the tuberculosis service. Only when that co-operation was fully forthcoming would tuberculosis become a really preventable disease.

### THE NEW PHARMACOPOEIA EXPERT WORK OF THE COMMISSION

The Pharmaceutical Society of Great Britain has arranged a series of lectures on the new *British Pharmacopoeia*. The introductory lecture was given by Dr C. H. Hampshire, secretary of the Pharmacopoeia Commission, on Oct. 28. Before him on the table were all the seven volumes of the *Pharmacopoeia*, the earliest a small volume in black binding dated 1864. Dr Hampshire touched first on the question of nomenclature. Apart from a few minor changes, he said, the nomenclature followed the system employed in previous volumes. An unfortunate position was created by the issue of the same drug under a variety of proprietary names given it by different manufacturers. The intention now was to provide non-proprietary names which could be used by all manufacturers, and if the drug was eventually included in the *Pharmacopoeia* the approved name would be given to it. The selection of drugs for inclusion was decided principally on clinical and

pharmacological grounds, but pharmaceutical knowledge was a factor in deciding on the manner of presentation and the inclusion of materials in the preparation. The desire was to make a book which would reflect the latest achievements of medical science and clinical research while at the same time recognizing old preparations which were still in use and required control. Thus it came about that many products of the modern biochemical laboratory were included side by side with senna, castor oil, aloes, and the like. A large number of authorities had been consulted, including the Committee of Revision of the *U.S. Pharmacopoeia* and the expert committees of the Health Organization of the League of Nations. The ideal pharmacopoeia would give for every drug prescribed a complete set of standards, tests, and assays for its control. The progress made to this end was considerable, but it had not been possible to avoid some gaps. Scientific research went on continuously, but in preparing a periodical volume there came a time when it was necessary to close down for publication, so that in some respects the book was quickly out of date.

The crude vegetable drugs, Dr Hampshire said, had been examined by an expert committee, and 11 of those previously appearing had been deleted on the ground of insufficient clinical importance. Cinchona was deleted as the result of a decision made by the Commission some years ago that this drug was to be regarded simply as the source of quinine, and that quinine was to be regarded simply as an antimalarial drug. Therefore certain tinctures, extracts, and so on of cinchona were removed, and some preparations of quinine had also been deleted. Drugs like linseed were dropped because better drugs were now available. Fresh infusions had been deleted owing to the fact that they were very seldom used, and plasters on the ground that it was no longer pharmaceutical practice to prepare plasters in a small way when much better preparations were produced on a manufacturing scale. The question of uniformity of size of tablets had been considered and an approach made to a definite standard for the purpose, but the information received made it evident that to introduce standards, with the necessary changing of dies and punches, would cause a great deal of inconvenience and expense at a time when this would not be justifiable.

The ointment of tannic acid had been included at a time when there was enthusiasm for unification with the *U.S. Pharmacopoeia* but this and other ointments had now disappeared and been replaced by better preparations. During the war attempts were made to economize fats and paraffins by producing ointments containing a considerable proportion of water. Only the best of these had been retained. The range included had been decided by a committee of dermatologists and pharmacists as giving different types of bases which doctors could use for the addition of any drug they required. Boric acid ointment had been reduced in content to 1%. This ointment was simply retained in the *Pharmacopoeia* as a protective, and it was just as good without the boric acid as with it, but as it was a popular remedy it was thought desirable to retain the name and justify it by the inclusion of this minimal proportion. The sections on penicillin complied with the regulations under the Therapeutic Substances Act, and were simply put forward as being in accordance with the present state of knowledge. In connexion with penicillin it should be noted that the standards were brought into effect by notices in the *Gazette*, it was possible now to make changes very quickly by that method. Vitamins A, B, C, and D, and of vitamin B complex the constituents aneurin hydrochloride, riboflavin, nicotinic acid, and nicotinamide, were all included.

The desire for unification in terminology and strength of composition had led to attempts from 1874 onwards to produce an international pharmacopoeia. An international conference at Brussels in 1925 reached agreement covering 77 potent drugs and preparations. Of these, 40 were not included in the 1948 *British Pharmacopoeia*, and of the 37 included, 25 complied with the requirements of the agreement and 12 differed in greater or less degree. The Health Organization of the League of Nations set up a technical commission in 1937 with a view to preparing a new international agreement, and an interim report was made. The war had delayed matters, but the formation of the World Health Organization offered an opportunity for the resumption of this work. An expert committee for the unification of pharmacopoeias met regularly at Geneva, and it

was hoped that a new international agreement would be forthcoming to meet the difficulties arising from different standards for drugs in different countries, which were especially troublesome and conceivably dangerous for travellers who had occasion to have a prescription dispensed in a country other than that in which it was issued

## SEX BEHAVIOUR OF THE MALE

### DISCUSSION ON THE KINSEY REPORT

A report on the sex life of some 14 500 American men has lately been published in the United States. This report, by Dr Alfred Kinsey, of the University of Indiana, is the first of eight volumes, and the second will be on the sex behaviour of the female. A meeting of the Planning Forum was held in London on Oct 27, when this report was the theme for discussion. The subject was introduced by Dr FRED GRUNDY, chairman of the British Social Hygiene Council who said that the inquiry had shown the enormous range of variability of sex activity among men, and it was claimed by the author that both the very low and the very high activity were found among people who were well adjusted and efficient citizens. On the whole the highest activity was found to be in late adolescence, and usually it dropped off slightly after the age of 30, though in many men it continued to an advanced age (85 was mentioned). Among Dr Kinsey's findings were that there was no real evidence that sexual activity could be voluntarily diverted to art, literature or other high-level activities, that sex activity tended to be higher in the subsequent life of males who attained puberty earlier than normal, that masturbation was more frequent among high school and "college educated" men while pre marital intercourse was more often found among those of ordinary school education, and that men of the lower occupational and educational groups more often found extra-marital sexual outlets during early married life but returned to marital faithfulness later, whereas the reverse was true at college level.

Dr Grundy said that Dr Kinsey had employed the interview technique. The sample taken was not a completely random one, it was what was known as a judgment sample. As these interviews were with persons who had attended a talk by Kinsey and had been willing to subject themselves to his technique, there was a possibility that in his anxiety to get a completely representative sample Kinsey had over-weighted his selection with people who were at one or other extreme or were perverted in their sex activities, though the experts believed that such errors, if they existed, made no serious difference to the final results. Dr Grundy thought that much the same pattern would be found in this country, though the incidence of homosexual practices would probably be rather less. Another question was whether Kinsey was justified in publishing results of this kind beyond a limited scientific circle, though he had not intended to make the report a "best seller". But in fact, said Dr Grundy, Kinsey had brought a breath of realism into the subject of sex behaviour which perhaps was not so much needed over here as it was in the States.

#### Interview Technique

Dr DAVID MACE, secretary of the Marriage Guidance Council, who had met Kinsey in New York and had subjected himself to his technique, said that the interview lasted fifty minutes, during which he was asked about 350 questions. Kinsey had an ingenious method of recording data using a card hardly larger than a postcard, and setting out the history in code to an extent which if written in full would occupy twenty five typewritten pages. He believed that Kinsey had done his best to get a complete cross section of the population, and he and his three colleagues had spared no pains to ensure the integrity of the inquiry. The report was a picture of sexual behaviour in a sexually sick society, for the disturbed state of family life in America needed no emphasis. Normal sexual behaviour which was the standard whereby these extremes and deviations had to be judged was difficult to define, but it might be regarded as the way in which men and women behaved about sex in a society enjoying a sound stable, and secure family life. One of the striking things elicited was the early development of sexual power in boys. It was disturbing

to find that the average man had masturbated from his early teens at the rate of two or three times a week and it seemed possible that while they had been teaching young people about the "facts of life" as illustrated in the animal kingdom their pupils were already engaged in sexual activity. He thought there was danger in the statement that pre marital intercourse did not cause any trouble in subsequent marital adjustment. A small inquiry in Marriage Guidance Council cases had shown that there was a greater tendency for people who had had pre marital intercourse to break away from the marriage when strains and stresses arose. No real answer could be given on this and other points until the investigation of female sex behaviour was completed for women suffered more than men from irregular sex relations.

Dr E H LARKIN said that none of his psychiatric colleagues who had taken sex case histories had expressed any surprise at the American figures. The report was not a psychological work, there was no attempt to equate the findings with the psychological state, but it contained many points of psychological interest as for example, that boys of 11, if they masturbated although they had no emission, had an orgasm. The finding that the earlier sexual activity began the greater was its persistence was correlated with the well known fact that in females in whom menstruation had begun unusually early the menopause was unusually late. One experience of the psychologist, hardly borne out by the Kinsey report, was that people who had most intense sexual pressure often lived most active professional or occupational lives. The subsequent discussion was noteworthy for the women speakers who attacked the Kinsey report for its non-idealistic outlook.

## EMPIRE RHEUMATISM COUNCIL NEED FOR RESEARCH

The annual general meeting of the Empire Rheumatism Council was held in the state rooms of St James's Palace on Nov 2. H R H the Duke of Gloucester, who presided, said that the council was at all times happy to place its knowledge and experience at the disposal of all interested bodies and persons. In industry alone it was estimated that three million weeks of work were lost each year by the insured population as a result of rheumatic disease, and that the annual cost of rheumatism was in the neighbourhood of £20 million.

Lord Horder, who was re-elected chairman of the council described the combating of rheumatism as "one of the major preoccupations of my life". He supposed he was too near to this particular crusade in medicine to say whether the Empire Rheumatism Council had justified its twelve years of existence. Its threefold purpose had been very carefully stated—namely, to organize research into the causes (not the cause) of rheumatic disease, to encourage education, both medical and lay, in the subject and to stimulate public authorities to provide treatment for rheumatic sufferers at as early a stage of the disease as possible. Remembering as he did the very considerable advances that had been made during the existence of the council in all these three fields, he thought it not too much to say that the council's share in them had not been a minor one.

Dr W S C Copeman, honorary medical secretary of the council gave a brief address on the need for research. Rheumatism, he said was a word difficult to define. Professor Hench, of the Mayo Clinic, in his recent visit to this country had stated that there were over 200 forms of so called rheumatism. Dr Copeman himself evaded a definition by reciting three typical cases from his own records. One was a fatal case of juvenile rheumatoid arthritis in a child of 7. Next to nothing was known of the cause of these cases and little enough about their treatment. The second case was one of swollen and painful joints in a working woman condemning her to hopeless bedridden crippledness—a condition which might have been relieved and possibly cured if it had been tackled in time. The third example was of spondylitis in a young naval officer. Dr Copeman said a few words about other serious forms of rheumatism—sciatica, neuritis, osteoarthritis—all major enemies of industrial life owing to the toll they took of health and working time. Rheumatic fever came into a

different category, attacking the heart muscle of its victims and being responsible for a very large proportion of heart disease in this country

Finally he made a plea that funds should be provided for specially trained workers and for laboratory and other equipment to assist research. If the council, he said, in addition to its present all too modest funds, could be assured of half the money which was justifiably spent on cancer and tuberculosis the answer to the question of rheumatism could be found. The Government gave sympathy but no financial support, and therefore he appealed for voluntary help, especially from industrialists and organized labour. He was sure that the result would yield dividends exceeding the most sanguine expectations.

## Reports of Societies

### CANCER OF THE CERVIX EARLY AND PRECURSORY STAGES

At a meeting of the North of England Obstetrical and Gynaecological Society held in Manchester on Oct. 8, with the president, Mr J. E. Stacey, in the chair, Professor EMIL NOVAK, of Baltimore, U.S.A., gave an address on 'Early and Precursory Stages of Cervical Cancer'.

Professor Novak pointed out that in the U.S.A. 18,000 women died from cancer of the uterus last year. The chief hope of reducing the death rate lay in the early diagnosis of established disease and the detection of precursory lesions. Although there were no dramatic advances to report, certain generalizations could be made. It was agreed that a cancer cell was a cell which had "gone wrong" and assumed a different and uncontrolled form of life. In this change heredity was an important factor, and this was borne out by animal breeding experiments and by human studies. It appeared that there were three classes of individuals: (1) those whose inherent predisposition was so strong that they were destined to suffer cancer irrespective of any other circumstances, (2) those in whom the predisposition was less well developed and who required exciting factors before the growth appeared (there might be many exciting factors, but so far as the uterus was concerned the possibilities were injury, infection, and oestrogenic hormones), (3) those who had no predisposition to the disease, and who would never develop cancer even when exposed to those activating factors which determined the onset of the disease in class (2).

The relationship of oestrogens and carcinoma was a difficult one to assess. Judging by the well-known effects of these hormones it was reasonable to suppose that they might cause cancer in susceptible women, but this effect could only operate in respect of the breast, uterus, vagina, and vulva. Reviewing experimental work on the production of breast cancer by means of oestrogens, Professor Novak pointed out that this disease had only been produced in mice, and the results had been negative in all other species. Cervical changes in animals following the administration of oestrogens were also reported, and it was of interest that these could be prevented by giving progesterone. Progesterone would appear to have some protective action against the carcinogenic effect of oestrogen. Although a study of biological hormonal effects and of the pathology of uterine carcinoma might make one hesitate to employ oestrogen therapy in the presence of a precancerous lesion or in a woman with a strong family taint of malignant disease, yet Professor Novak did not know of a single case in which oestrogens had been shown to have been the cause of cancer in women.

#### Precancerous Lesions

Professor Novak went on to discuss some pathological features with particular reference to precancerous lesions. Leukoplakia of the cervix, a condition first recognized and described as a result of colposcopic studies by Hinselmann, was now generally accepted as not predisposing to malignant change. The most important lesion was intra-epidermal carcinoma, or Bowen's disease. In this the cells of the epidermis showed malignant characters but the condition might remain localized for many years before ultimately breaking through the basement membrane to assume typical malignancy. Professor

Novak said that in his experience, when this condition affected one part of the cervix, then it was common to find fully established carcinoma in another part, provided a thorough search was made. Nevertheless, routine and careful examination should make it possible to detect and treat this condition while it was still localized. Amputation of the cervix was probably sufficient to deal with it adequately, although in his clinic total hysterectomy was usually carried out—partly for the purpose of having all the material for study and research. Another change in the cervix which might be significant was unusual activity of the basal cells of the epidermis. This might be a reaction to a hormonal stimulus. Such a change and even pseudo-malignant features were to be seen in the cervix sometimes during pregnancy. These changes were reversible and might well be associated with the profound hormonal changes of pregnancy.

Discussing the early diagnosis of malignant and pre-malignant states, Professor Novak referred to the newer techniques. The Schiller test with iodine had little application, since it indicated merely the site of pathological change and not its nature. Vaginal smears were in vogue but were extremely difficult to interpret, even the few experts admitted a comparatively high proportion of errors in diagnosis. He considered that cervical biopsy still remained one of the most reliable methods but advocated a modification, namely "surface biopsy" in which large areas of the superficial layers of the epithelium were removed by scraping with a curette or sharp spoon. This technique was most satisfactory for revealing intra-epidermal carcinoma. Finally Professor Novak referred to the difficulty of making a diagnosis of carcinoma on histological grounds. This applied to endometrial as well as cervical studies. There were many borderline cases. He illustrated these and other points by photomicrographs of cervical and endometrial tissue.

The president and Sir William Fletcher Shaw, speaking on behalf of the Society, both thanked Professor Novak for his interesting and instructive address, and Professor Novak replied.

### TREATMENT OF THYROTOXICOSIS LIVERPOOL MEDICAL INSTITUTION

At a meeting of the Liverpool Medical Institution on Oct. 21, with Dr H. H. MACWILLIAM, vice-president, in the chair, a discussion took place on thyrotoxicosis.

Mr PHILIP HAWE said that five years had elapsed since the introduction of the thiouracil compounds and still there was no unanimity of opinion about their value. To provide a standard against which the results of thiouracil therapy could be judged the records of two series of cases operated on by the speaker at the David Lewis Northern Hospital, Liverpool, were analysed: (a) a post-war series of 86 cases (1945-8), and (b) a pre-war series of 78 cases (1936-9). Carcinoma was found on pathological examination in three cases. The average hospital mortality rate was thought to be substantially above 0.5% (this did not refer to patients prepared for operation with thiouracil). There were three deaths among the 164 cases analysed, all were poor-risk patients with long-standing nodular goitre.

The efficiency of the operation was illustrated on the basis of a recent 'follow-up'. In both series the results were highly satisfactory—almost 90% of the patients were capable of normal duties six months after operation, and, allowing for advancing years, there was evidence to show that these results were maintained for at least nine to twelve years. Exophthalmos was slow to improve in the post-war group, but in the pre-war series the eyes had with few exceptions greatly improved or returned to normal. Of the 18 cases with fibrillation 15 returned to a normal rhythm after operation and remained normal over long periods. A group of 6 pre-war adolescent patients was found to be very well indeed with the exception of one who suffered from mild hypothyroidism. Of 78 pre-war cases 8 developed hypothyroidism—4 severe and 4 mild—and recurrence occurred in 3 cases. The early results of thiouracil were thought to compare favourably with those of surgery, but would these good results be maintained through the years as they were after operation?

Dr LESLIE CUNNINGHAM pointed out that the discovery of the effect of thiouracil introduced a new principle in practical therapeutics. For the first time it appeared possible to control

disease by preventing with drugs the formation of a hormone. Results of thiouracil therapy were discussed, and the favourable cases included one of auricular flutter which responded to thiouracil alone in three weeks. Contraindications appeared to be the previous occurrence of agranulocytosis, intrathoracic goitre and cases in which there was evidence of pressure phenomena, hyperophthalmopathic Graves's disease, suspected malignant disease, and cases of thyrotoxicosis in which the temperament and economic circumstances contraindicated a prolonged and tedious treatment. The treatment of post-operative auricular fibrillation by means of quinidine was described. Out of 9 cases 8 responded very rapidly, 2 responded after thiouracil had been given as well, and without operation.

Professor CHARLES WELLS thought there was a tendency to minimize the risks of thyroidectomy and that extremely low mortality figures could be obtained only by rejecting a number of bad risk cases. Up to a couple of years ago he had had a long series of cases with almost no mortality but in the last two years he had had a few unexpected shocks. Two cases in the treatment of which he was concerned were examples of gross nodular goitre in elderly women without recognizable toxic manifestations. In each case a severe post-operative crisis developed.

### Thyroidectomy or Thiouracil

Professor HENRY COHEN recalled that in the symposium on thyrotoxicosis ten years ago which he had the privilege of opening there had been general agreement that thyroidectomy was the treatment of choice but it was recognized that the operation was based on the primitive and barbaric principle of cutting off the offending part, and the hope was expressed that with the unmasking of causative factors non surgical methods of treatment would be discovered. We still remained ignorant of essential factors in the causation of thyrotoxicosis. The clinical picture of the victims of thyroid addiction showed that thyrotoxicosis and hyperthyroidism were not synonymous, though the former included the latter. Moreover, the various patterns of thyrotoxicosis suggested that it might be the expression of more than one aetiological factor and that the susceptibility of different tissues to thyroxine, and their capacity to use it might well modify the clinical picture. Thiouracil and radio active iodine were most valuable both in treatment and in pre operative care, but they did not attack extra-thyroid causative factors. Thiouracil had its toxic hazards and might produce, from swelling of the goitre, mechanical disabilities demanding urgent surgical intervention. Moreover, there was always a risk of overlooking the malignant thyroid with thyrotoxicosis if medical treatment alone were advised. But there was a real place for thiouracil in the therapy of thyrotoxicosis, and Professor Cohen subscribed to the indications laid down by Dr Cunningham, and mentioned the benefit which had followed the exhibition of oestrin in large doses in a few severe cases of exophthalmic ophthalmoplegia.

Mr A M ABRAHAMS said that the symptom of exophthalmos was caused by (a) lid retraction and (b) true exophthalmos. It was usually the former that improved. One case in 250 had increased exophthalmos after operation, excision of the retrobulbar fat improved the condition. Auricular fibrillation had occurred in 19 cases of the series of 250 he had reviewed (8%). This ceased in 6 cases within three weeks of operation and still persisted only in 3 cases. The results of operation were excellent in 187 (77%), good in 46 (19%).

At a meeting of the Devon and Exeter Medico Chirurgical Society on Oct 26 Dr Horace Evans concluded a review of hypertensive disease with special reference to its surgical treatment by saying that as a rule operation should not be undertaken on patients over 50. Certain unpleasant sequelae must be anticipated, the most important of which was sterility in young male subjects. In a series of about 100 cases treated surgically it was fair to say that in most of them the operation had been worth while, though only a few had shown dramatic improvement. Sympathectomy apparently cured retinitis and it undoubtedly relieved symptoms especially headache. Very few men were still alive four years after operation but this was a considerably longer prognosis than that to be expected without operation. Operation also provided a possible alternative to the termination of pregnancy in hypertensive expectant mothers.

## Preparations and Appliances

### WALKING-APPLIANCE FOR LOWER LIMBS IN PLASTER

Dr A R THOMPSON, Medical Officer of Vauxhall Motors and Mr L W PLEWES, Surgeon to the Orthopaedic Clinic, Luton and Dunstable Hospital, write: The ideal walking appliance for patients with a leg in plaster has not yet been found, although improvements are constantly being developed. This problem was put to the rehabilitation unit at Vauxhall Motors, Luton, several years ago and under the guidance of the engineer director, Mr Newell and his assistant, Mr Trussell, a boot has been designed and used successfully for the past eighteen months in 70 cases.

Using scrap leather, 1-in (2.5 cm) "sorbo," and elmwood soles, these boots are made by the patients themselves in the Centre. Their weight varies from 1½ to 2 lb (0.68-0.9 kg) according to size. The accompanying illustrations show the design in some detail.

FIG 1—Diagram illustrating the principle of the boot. The strap A is incorporated inside the boot to secure the plaster cast firmly within.

FIG 2—(A) The elmwood sole has been fitted with three bars of hard rubber. (B) One inch sorbo has been fixed on to the top of the wooden sole. (C) Scrap leather has been used to cover the sorbo.

FIG 3—The finished boot, showing three strong straps to keep it in place.

One of the distinct advantages of this appliance is the relative normality of gait which is possible. Not only is the natural heel and toe action permitted, but the sorbo gives a springiness to the gait which is so apparently missing in the usual rocker arrangement. Other advantages are the smart appearance and the removability of the boot, which saves bed linen.

One difficulty which was soon overcome was the slight alteration in skin-tight plaster technique necessary when the boot is to be used. The sole of the plaster cast should be as nearly flat as possible and reinforcement of the cast at the ankle and just above the ankle was necessary. Another problem was the discomfort along the front of the leg, as the weight is borne by the front of the foot. A felt pad 2 in (5 cm) wide placed along the subcutaneous border of the tibia proved satisfactory.

We wish to pay tribute to the Vauxhall Rehabilitation Unit for the interest, care, and ingenuity shown in the development of this successful walking appliance.

## Correspondence

### New South Wales Branch of B.M.A. and R.M.B.F.

SIR,—In your issue of Jan 3 (p 28) you published a letter from me informing the profession that the members of the New South Wales Branch of the British Medical Association were sending food gift parcels to beneficiaries of the Royal Medical Benevolent Fund.

I would like to make further public acknowledgment of their generous action and to report that up to date our beneficiaries have received four or five gift parcels addressed directly to each of them. This makes the wonderful total of over 2,500 parcels altogether. Your readers can imagine how grateful the recipients feel and how deeply touched they are by the kind thought of professional colleagues so many thousands of miles away. I have written to the members of the New South Wales Branch telling them that their action makes them very near and dear to us—I am, etc.

WEBB JOHNSON,  
President  
Royal Medical Benevolent Fund

### Tudor Edwards Memorial

SIR,—In the *Journal* of June 7, 1947 (p 821), you were good enough to publish a letter inviting contributions to a fund for the establishment of a memorial to the late Mr Arthur Tudor Edwards, M.Ch., F.R.C.S.

The fund was closed on March 31 last and reached £4,000, with which the Royal College of Surgeons of England and the Royal College of Physicians have consented to form and administer a trust to found a Tudor Edwards Lectureship to be given alternately at the two Colleges.

It is hoped that the lectures will reflect Tudor Edwards' wide interest and that they will embrace not only the surgery and medicine of diseases of the chest but also the allied studies of anatomy, physiology, pathology, and anaesthetics applicable to thoracic surgery.—We are, etc.,

HORDER (chairman),  
COURTAULD-THOMSON (treasurer)

London W 1

### Femoral Hernia

SIR,—I feel I must reply to the remarks in your annotation on femoral hernia (Oct 23, p 750) regarding the use of the low approach in cases of strangulation and I must disagree with the statements that "it is very hard to justify a low approach in cases of strangulated femoral herniae" and that "the low approach may give a totally inadequate view of the strangulated viscus."

All are agreed that the contents of the sac must in every case be carefully examined and the viability of the bowel ascertained before returning it to the abdominal cavity, but this I contend can adequately be carried out from the low approach. The sac having been defined and opened the cause of the strangulation either the lacunar ligament or the narrowness of the neck of the sac itself (the latter being the more frequent in my experience), is freed and the loop of imprisoned bowel delivered into the wound—as much as is necessary can readily be brought outside and the constriction rings especially examined for viability. If viable the bowel is returned and the repair continued in the usual way. Should resection be decided upon (this is a comparatively rare occurrence, the vast majority of cases do not require anything further than relief of the constricting agent—in the series reviewed under "required resection"), then in my opinion this can be more readily and more safely performed through a separate paramedian incision.

It has been my experience that even in a Richter's hernia there is little danger of the bowel slipping back through the femoral ring before it has been brought into full view and its viability ascertained and even though this should occur (I recall a rarity) it is quite a simple matter to open the abdomen and thus be enabled fully to inspect this loop of bowel.

I have used the low operation for strangulated femoral herniae over a large series of cases and with very few troubling complications. In the majority of strangulations the

operation has proved to be a simple and straightforward procedure and is especially suitable for frail and aged subjects—local analgesia being all that is required. It is worth noting in this connexion that the average age for a strangulated femoral hernia is between 63 and 64.

Obviously no operation is without its own particular drawbacks, but surely it is wise to select the one which is the simplest and the most straightforward and at the same time the one which gives the most gratifying end-results. (In a careful follow-up there was no increased rate of recurrence in the strangulated as compared with the non-strangulated cases.) This is the claim I put forward for the low operation. It would indeed be most interesting and enlightening to hear other surgeons' views on this point—I am, etc.,

Bedford

ANDREW G. BUTTERS

SIR,—As one who has practised the "low" repair for femoral herniae for some years to the total exclusion of all other methods I welcome Mr Andrew G. Butters' article (Oct 23, p 743) and find myself in agreement with most of what he says. That the cleansing and freeing of the neck of the sac, so as to allow good retraction following transfixion and removal of the sac, is the most important step cannot be too strongly emphasized. I am opposed to the "high" operation in view of the unnecessary damage inflicted on the inguinal canal.

I do, however, disagree with him and with the annotation on this subject in the same issue (p 750) that the abdomen should be opened through a separate incision should resection of bowel be necessary in strangulated femoral herniae. I have always carried this out through the "low" approach and have found this safe, adequate for visualization of the afferent and efferent limbs of the affected bowel, and readily accomplished under local anaesthesia.

Peritonitis from incompletely inspected strangulated Richter's hernia which the annotator describes and which he uses to condemn the approach, should surely reflect on the inspector rather than the operation used—I am, etc.,

Isleworth, Middlesex

J. SCHOLEFIELD

### First Conference of Industrial Medical Officers

SIR,—The preoccupations of the Ninth International Congress on Industrial Medicine prevented my reading Sir George Schuster's paper in the *Journal* of Sept 11 (p 505) until recently. In paragraph 29 Sir George refers to the first conference of industrial medical officers in 1921 as having been convened by the late Sir Thomas Legge. In the interests of historical accuracy may I point out that that conference was convened by the Industrial Welfare Society and was opened by H.R.H. the Duke of York, now H.M. the King?

It is right to say that the late Sir Thomas Legge together with Sir Thomas Oliver and others were sources of great encouragement and support to that conference, and indeed it was Sir Thomas Legge who suggested the holding of such a conference to Mr Robert Hyde, the director of the Society—I am, etc.,

London W 2

T. E. A. STOWELL

### Pensions for Diabetics

SIR,—I should like to air my opinion about the hundreds of claims for pensions by Servicemen who have developed diabetes while in the Forces, particularly as more than a hundred have been referred for my opinion as to whether Service hardships shocks, or wounds are aetiological factors. This problem is no new one, as diabetes discovered after accidents in civil life is a common source of litigation. In such cases there has seldom been a urine test for long before the accident to prove that diabetes was not present before that accident. But Service cases are different.

Diabetes in recruits is normally excluded by a urine test, and so, if and when they develop diabetes in the Forces, they conclude that their service has caused it and that they should be pensioned. Some have gone through wounds and hardships, others have never left this shore, but too many of these cases find something—a knock, a cold winter, bad food—to which they ascribe their diabetes.

The scientific and considered medical opinion in every country finds no evidence that trauma, shock, physical or mental strain, exposure, or climatic conditions are causal factors in the aetiological mysterious disease diabetes, though factors of heredity and previous obesity are well recognized. This opinion grows stronger with more experience. Both major wars produced no increase in diabetes, and London with its tensions and 'blitzes' shows no increased incidence. A phrase in my book, *The Diabetic Life* 'When shares go down in Wall Street diabetes goes up' (p 10) partially contradicts this. I must confess that this sentence was copied from another writer into my first edition in 1925 when I knew little and has remained there too long. I shall expunge this phrase from future editions. Factors of worry can sometimes increase the sugar in established diabetics but, I think, never *per se* are a clear primary cause, otherwise the majority of humanity would become diabetic. So let me repeat that I think war claims for pensions for diabetics are unfounded on fact.

The expense to the State of tribunal appeals and High Court litigations must be considerable, probably thousands of pounds to the taxpayer. I should mention that many times the British Legion too presses for compensation in such cases and approaches me for supporting certificates. These I cannot provide on factual grounds, as I consider that diabetes must be looked upon aetiological in the same light as cancer or leukaemia.

And after all is diabetes a disability requiring or worthy of a pension, award, or support? The Council of the Diabetic Association, a sympathetic body of lay diabetics has often considered appeals to support claims for pensions and has refused—this on the ground that adequate treatment and co-operation in it by the diabetic produce normal health and no real important disability in work or life—I am, etc.,

London W1

R D LAWRENCE

### Forequarter Amputation

SIR—If it is not too late I should like to refer to Dr J D C Millar's interesting memorandum (Sept 18, p 559), which I overlooked. There is in fact a good deal of literature on the subject of forequarter amputation, particularly a comprehensive monograph by Paul Berger,<sup>1</sup> the French surgeon whose name has for so long been associated with the classical operation. In Berger's book are to be found the histories of many cases of traumatic amputation as well as amputation for pathological conditions. It would seem that most of the cases have been recorded by British surgeons, one of the first mentioned being Cheselden's case to which Mr J Dudfield Rose (Oct 16 p 722) draws attention. A case in recent times similar to Dr Millar's is that recorded by Drake Lee and Frank Radcliffe.<sup>2</sup> It is worthy of note that in the majority of these cases there is little haemorrhage but much shock, and that while the scapula comes away with the arm the clavicle remains attached to the body. The case of avulsion of the hindquarter recorded by Dr Protheroe Smith (Oct 2, p 662) is indeed a remarkable one, perhaps the first on record.

According to Berger there has always been great controversy as to who was the first to perform forequarter amputation. Claims were advanced on behalf of Cheselden because of the case mentioned above and on behalf of Baron Larrey, Napoleon's famous surgeon, who accompanied the Emperor's armies on five different campaigns. Eventually credit was given to Ralph Cumming, a surgeon-captain in the Royal Navy, who performed the operation on a young sailor aged 21 at Antigua in 1808. Cumming did not publish his case, but a letter from A Copland Hutchinson with reference to it was published in the *London Medical Gazette* November, 1829. The letter was treated with scant respect by a Scots reviewer, who wrote a blistering comment on the data supplied.

I was interested in the subject some years ago, and reference to the naval records showed that there was no doubt whatever that Cumming performed the operation but the only note he made at the time was 'amputation of the shoulder'—a brevity in keeping with the silent Service. The operation took place in March 1808 and the sailor arrived back in England in the autumn of that year and reported to the Naval Hospital at Greenwich. It was found that complete forequarter amputation had been done—arm, scapula, and clavicle, all had gone

It would appear also from the records that the surgeon-captain drew the highest pay of any officer on the station. *O tempora O mores!*

The Berger or classical operation continues to be described in detail in surgical textbooks, but it is open to question if it is the best operation. To say the least of it it is not an easy one to perform. The essential feature of the method is control of the main vessels at the outset. The middle third of the clavicle is resected to allow of exposure of the subclavian artery, here situated behind the vein, the artery is divided between ligatures, the arm elevated to empty it of blood, and the vein is then likewise secured. While this procedure may be an interesting anatomical exercise on the cadaver, it may prove a difficult if not a dangerous step in the living particularly when one is dealing with a large tumour and engorged veins. All this is done with the object of conserving an arm full of blood, a questionable procedure now that blood transfusion is a commonplace of surgery. Besides, it is more than doubtful if ligature of the subclavian artery at this site fulfils its object, for it certainly does not control the arterial anastomosis around the scapula.

In fact it will be found much easier and quicker to perform the operation from behind, following the method carried out originally by McGill<sup>3</sup> of Leeds, and later given in detail in the *British Medical Journal* by Littlewood,<sup>4</sup> another Leeds surgeon. It will be found too that there is not any more loss of blood than in the Berger method. If for any reason the posterior method is not advisable then a modified anterior approach can be used by first dividing the pectoral muscles and getting control of the axillary vessels as high as required. This exposure also gives access to the subscapular artery, which plays a large part in collateral circulation. The clavicle can then be divided and the vessels controlled higher up if necessary.—I am, etc.,

London W1

### H11 in Malignant Disease

SIR,—As a general practitioner who has used H11 to a limited extent but with encouraging results I was interested to read the report from the Medical Research Council (Oct 16 p 701) and the leading article on this subject (p 716). I must admit, however that I was not impressed with the completeness of the investigation, and I do not therefore feel that the conclusions reached are justifiable.

The committee states, "To attempt to follow up the subsequent life histories of the patients by inquiry of general practitioners would involve an amount of time and labour incommensurate with the results likely to be achieved." I would respectfully suggest that this is the only satisfactory method of reaching a conclusion on the efficacy of H11 in the treatment of human cancer. In your leading article is the amazing statement, "Few general practitioners will see more than three or four cases of cancer a year." As a partner in a busy industrial practice a conservative estimate of the number of cases seen by me in a year would be fifteen to twenty.

I have personally used H11 in the treatment of three cases to date. One patient, a woman with carcinoma of the ovary with massive peritoneal and pelvic secondaries died of intestinal obstruction within three months but I feel her case was quite hopeless from the start and H11 was employed as a last resort. The other two cases are alive and comparatively fit. One, a case of bronchial carcinoma confirmed by bronchoscopic biopsy, shows clinical and possibly radiological improvement, but he has only been under treatment for five months and requires more prolonged observation to assess the results of treatment.

The remaining case is that of a man of 42 with carcinoma of the rectum who has been under continuous treatment with H11 since March 1947. His case is of great interest and I hope to publish full details at a later date. We had a laparotomy in March, 1946 when the diagnosis was confirmed by biopsy, but owing to two palpable nodules in the liver, thought to be due to secondaries, only a colostomy was performed. Treatment started with H11 in March 1947 and his clinical condition improved to such an extent that a further laparotomy was performed in January, 1948, when, as so

econdanias in the liver or elsewhere could be detected an abdomino-perineal excision was performed. This patient has recently returned to work in good health. He is continuing with H 11 therapy.

Nobody suggests that H 11 should be used as a substitute for surgery or radiotherapy, but the general practitioner is called upon to look after most cases of malignant disease abandoned as hopeless by the consultants. I would therefore make a plea for a thorough investigation of the effects of H 11 therapy on their patients by general practitioners. I consider that failure of the Medical Research Council to enlist the assistance of general practitioners largely vitiates the value of their conclusions. My own results, although not conclusive, are encouraging enough in my opinion for me to continue to employ this agent in the hope at least of relieving pain and distress and possibly of prolonging life. If this hope is not fulfilled in the future I can assure you I shall abandon this therapy as I have many others in the realm of medicine. At the moment, however, I consider the treatment *sub judice*—I am, etc.,

Birmingham

H JOSEPHS

SIR—To those observers who have recorded a conspicuous success with the use of this agent the uncompromising report of the Medical Research Council's committee (Oct 16, p 701) will come as a great disappointment. Surely an agent that has cured a few hopeless cases calls for a more systematic clinical trial at a research centre rather than so curt a dismissal?

It seems to me right that all cases of cancer, confirmed by biopsy, that have been successfully treated by H 11 should be reported in the medical press immediately. The astonishing case of carcinoma of the bladder which I reported in the *Journal* of Aug 14, 1943 (p 211), has remained in the full enjoyment of health and has again undertaken work of serious responsibility. His survival since the commencement of H 11 treatment is now 6½ years. There is no doubt whatever that he owes his life to changes in his state which started a few days after H 11 was first used and continued progressively. I have used the treatment in five subsequent cases where the diagnosis has been confirmed by biopsy. In one breast cancer the progress of the disease was arrested, death taking place later from cerebral haemorrhage. In another similar case progress is retarded—I am, etc.,

Farnham Surrey

FREDERICK CURTIS

### Classical Caesarean Section

SIR—With regard to the correspondence in your columns about caesarean section, although my experience of the operation is probably not so extensive as your other contributors I feel that in the classical operation a great deal depends on careful sewing up. I learned my technique from the late Mr Louis C Rivett whom I admired as a very gracious man and a most expert operator. He used good thick silk for at least one layer of mattress sutures, and he was most careful to approximate the whole thickness of the uterine wall.

The tendency is still very often to exhibit speed in this operation and in the presence of the usual free bleeding in the wound and with the fear of the suture going right into the uterine cavity it is easy to fail to get down to the uterine endometrial layer exactly. The wound can be quite successfully closed at the time and yet considerable gaps might easily thus be left in the thickness of the uterine wall. Following the Bornev-Rivett technique of course several layers are in reduced leaving as everyone knows a large ridge of uterine wall. I should have thought that barring accidents such as careful sewing up would leave a very sound uterus, as indeed, I should almost venture to say, does happen in a very large percentage of cases.

The use of spinal anaesthesia for the operation encourages one to operate leisurely and also I think reduces haemorrhage to a considerable extent. The use of ether if anyone uses it to-day, is of course as in other operations where free bleeding is less intense than bleeding. Perhaps what I have said is of interest to all experienced operators but I think that it may be well to draw attention to these points—I am, etc.,

N BEATTIE

### Hereditary Haemorrhagic Telangiectasia

SIR—I read with interest Dr C P Petch's account (Oct 30, p 785) of a case of hereditary haemorrhagic telangiectasia. Although uncommon, I have in my own experience encountered six cases during the past four years, and in my opinion the incidence of the disease is greater than might be expected from the number of published reports. The anaemia in the case described was the result of repeated epistaxis, the usual source of bleeding in such cases, attention is thus focused on the site in which the telangiectases are most frequently situated, and their presence is unlikely to be overlooked.

Nose bleeding is, however, sometimes absent throughout, as occurred in a recent case which came under my care. The patient had been treated for anaemia for ten years and complained intermittently of periods of extreme fatigue, palpitation, and dyspnoea. Investigation at a general hospital had shown no abnormality. Regular blood counts had been carried out during the six months before she was referred to my out-patients. The first gave the picture of a megalocytic anaemia, anisocytosis, poikilocytosis, and numerous normoblasts were present. Treatment with liver had resulted in a maximum reticulocyte response of only 17%.

The diagnosis was based on the association of telangiectasia on the lips and tongue with a sudden drop in the blood count from R B C 4,470,000, Hb 70%, to R B C 2,790,000, Hb 44%, in one week. This change was unassociated with overt blood loss or evidence of haemolysis. The stools gave a consistently strongly positive benzidine reaction, which was unaltered after treatment for 10 days with rutin, 80 mg tds. The ineffectiveness of this preparation in controlling bleeding accords with Dr Petch's experience.

An increased awareness of the disease and a careful scrutiny of the lips and mouth in every case of anaemia in which the cause is not clearly apparent may well bring many new cases to light and permit of rational instead of haphazard treatment—I am, etc.,

Guildford

HEWARD BELL

### Therapeutic Abortion

SIR—May I refer to the report which you gave recently of a medical trial which had caused considerable interest—that of Drs Eleanor Bergman and Mary Bell Ferguson, who were acquitted at the Old Bailey in May, 1948, of a charge of criminal abortion (May 22, p 1008).

Both the public and medical accounts of this case failed to report that Mr Justice Morris has given real assistance to the medical profession by enlarging upon the principles established in the Bourne case and by generally clarifying the practitioner's position in relation to the practice of therapeutic abortion. During the long and careful summing-up of this case the judge quoted the following words from the Bourne case:

'If the doctor is of opinion, on reasonable grounds and with adequate knowledge, that the probable consequence of the continuance of the pregnancy will be to make the woman a physical or mental wreck, the jury are quite entitled to take the view that the doctor who, under those circumstances and in that honest belief, operates is operating for the purpose of preserving the life of the mother.' He added "I fully adopt those words and invite you to bear them very much in mind."

Moreover, he told the jury, "You are not concerned with the question as to whether Dr Ferguson arrived at the right conclusion; you have not to decide whether Dr Ferguson did or did not make a mistake. Between medical people there may often be differences of opinion; sometimes it is difficult to assert which of two opinions is to be preferred; but you are not here to weigh up whether Dr Ferguson was correct or incorrect in the view that she had formed. You have to be satisfied by the prosecution that she expressed a dishonest opinion, and that when she advised if you think she did advise the termination of pregnancy by her letters in these two cases, you will have to consider whether you are persuaded by the evidence called by the prosecution that that lady gave a dishonest opinion, did not act in good faith, and was therefore advising something that was unlawful."

The medical position in the future is, therefore, greatly clarified. Provided that the practitioner who recommends the termination of pregnancy can satisfy a jury that his opinion was given "in good faith" he will not be expected to produce

irrefutable proof of the validity of his medical opinion—a point occasionally so difficult that practitioners have been known to hesitate to give consent in cases where their clinical judgment would have favoured termination.

These matters are clearly of importance to the medical profession, and we trust you will make them available to your readers. The Abortion Law Reform Association possesses a few copies of the summing up of Mr Justice Morris which could be borrowed by interested readers—I am, etc.,

ALICE JENKINS

Abortion Law Reform Association

53 Gloucester Terrace London W2

### Neonatal Asphyxia

SIR,—Dr W N Leak (Oct 30, p 797) refers to the work of the late Sir Joseph Barcroft and his associates on the foetal circulation and especially their discovery that in the case of the sheep it is the nasal area which receives the first stimulus at birth and thus initiates inspiration. In the lower mammalia the sensory area of the nose often extends over the alae and is not as in man chiefly confined to the inside of the nostrils. I do not know whether the stimulation of the nose of the newborn lamb is tactile, thermal or olfactory (that is to say to the sensation of smell), but the nose of man is certainly a poor receptive organ compared with the nose of the lower mammalia.

It has long been the practice of obstetricians to use carbon dioxide as a means of resuscitating asphyxiated infants, but it seems to me to be idle to suppose that any of this gas can be absorbed through the nose to reach the respiratory centre, and it cannot be expected to reach the circulation through the unexpanded lungs. Nevertheless, it is the experience of many of us that carbon dioxide is beneficial, and I suggest that its action is purely a local one of sensory stimulation. The tickling sensation experienced in the nostrils when we essay to drink an effervescent liquid is not due solely to the bursting of the bubbles of liquid containing gas but to the gas itself, and the same sensation is produced by blowing a current of dry carbon dioxide on to the nasal mucous membrane from a sparklet apparatus. Like Dr Leak, I am astonished that this physiological principle has been so far omitted from obstetrical textbooks—I am, etc.,

Whitnash Essex

W RADCLIFFE

SIR—Dr W N Leak (Oct 30, p 797) is to be congratulated upon the admirable way he reminds us of the late Sir Joseph Barcroft's brilliant researches into the physiology of neonatal respiration. It is unfortunate that there is still so little liaison between physiologists and clinicians, not only for their own sakes but because patients are often unable to benefit from the results of physiological research until many years after these have become common knowledge among non-clinicians. In this respect I agree that it is astounding how many authorities are ignorant of, or prejudiced against, a physiologically rational treatment of neonatal asphyxia such as that mentioned by Dr Leak.

The most frequent criticism is that cerebral stimulants will encourage the respiratory centre to metabolize the last remaining molecules of oxygen available, with still further depression of the centre and that should these stimulants prove ineffective other methods will fail owing to the anoxic condition of the centre. Presumably this is what is meant by the 'sadistic attacks' quoted by Dr Leak as occurring in a pre-publication copy of a new textbook. The answer is of course that injections of cerebral and respiratory stimulants ('cardiazol', 'ephedrine', 'alpha-lobeline', 'nikethamide') into the circulation via the umbilical vein or the heart itself in desperate cases so rarely fails to initiate respiration that the above criticism rarely applies—in any case should the baby fail to take a breath on its own the last few molecules of oxygen will be used up anyway and to no effect.

Dr Leak suggests that the basic pattern of respiratory response to sensory stimuli—the exteroceptor impulses from the skin, proprioceptor impulses from muscles, and enteroceptor impulses from internal structures—may persist long after birth and into adulthood. With regard to the skin painful stimuli

and sudden douching with cold water are known as respiratory stimulants even to laymen. It is not generally recognized however, what a large part proprioceptor impulses may have in reflexly affecting respiration. Physiologists now regard these impulses as responsible for the greater proportion of the hyperpnoea of exercise,<sup>1</sup> and Dr Carl F Schmidt,<sup>2</sup> professor of pharmacology of the University of Pennsylvania, goes so far as to suggest that the very existence of muscle tone itself is sufficient to maintain a continual reflex bombardment of the respiratory centre which combines with carbon dioxide and other reflex stimulation in maintaining the "tone" of the respiratory centre. It has been proved experimentally that even passive movements of muscles (whose blood supply is isolated from that of the parent body) will stimulate respiration, which makes one feel that Sylvester's method of artificial respiration in adults may be the most rational of those available. In addition one wonders whether keeping newborn babies still prior to the initial respiratory effort is quite as reasonable as was hitherto supposed.

Anaesthetists may be interested to note that Dr Schmidt's theory may have some bearing upon the respiratory depression which accompanies high spinal analgesia. In some cases this depression commences before any of the intercostal muscles are paralysed, and one explanation might be the progressive cutting off of sensory impulses from the periphery, which are then no longer available to bombard the respiratory centre—I am, etc.,

A H GALLEY

### Large-intestine Colic

SIR,—I was interested in Sir Heneage Ogilvie's article on colic due to sympathetic deprivation (Oct 9, p 671). May it not be that the syndrome was caused by irritation of the coeliac sympathetic nerves by the tumour cells rather than by deprivation? On this supposition the irritation of the sympathetic nerves produced spasm of the sphincter ani and atony of the colon, as actually seen in one barium enema on Case 1 and as evidenced by the lower abdominal distension in both cases.

The cramp-like pains and increased peristalsis represented the attempts of the intact parasympathetic system to overcome the obstruction. Because the pain pathways through the sympathetic were intact these cramps were painful. I offer this as a suggested explanation and not in any dogmatic way—I am, etc.,

### Breast-feeding

SIR—I would like to suggest as a possible cause of the failure of lactation the unnatural sleeping arrangements of mother and baby in hospital. Breast feeding is an intimate love act between mother and baby and should be followed by a satisfied sleep together in the warm intimacy seen in animals. Instead of this the baby is removed from its mother and put in an isolated cot (frequently in another room). This is emotional privation and often agony to the mother, who dares not protest against the accepted order of the hospital for fear of victimization by the nursing staff. The anxiety which inevitably follows is well known to cause suppression of lactation—I am, etc.,

RACHEL PINNEY

### Out-patient Electric Convulsion Treatment

SIR,—In the hope of encouraging Sir W P Mallinson to make better use of the out-patient facilities at St George's Hospital I want to ask a few questions and make some criticisms of his paper on electric convulsion treatment (Oct 2 p 641).

Dealing with the problems in the order in which Sir Paul discusses them there is first the question of technique. There is no uniformity at clinics throughout the country in respect of restraint of the patient during the convulsion, the administration of oxygen, or in the type of "box" used. Each clinic claims that its particular degree of restraint, or the absence

## 'AVLOPROCIL'

### Procaine Penicillin Oily Injection

'Avloprocil' contains the procaine-salt of Crystalline Penicillin in oily suspension and offers important advantages to both doctor and patient —

- Therapeutic blood levels of penicillin maintained for at least 24 hours
- Effective penicillin therapy achieved with a *single daily injection*
- Administration comparatively free from irritation and pain

*10 c.c. vials (300,000 units of penicillin per c.c.) Singly and in boxes of 5*

## HEPARIN (EVANS)

THE prevention of stasis and thrombosis ensures that continuity of circulation through the blood vessels which is essential to the welfare of the living tissue

Heparin—the physiological anticoagulant—is indicated for the prevention of thrombosis and allied conditions

Heparin (Evans) is a pure pyrogen-free preparation evolved at The Evans Biological Institute.

Rubber-capped bottles of 5 c.c. containing 5 000 i.u. or 1,000 i.u. per c.c.

Heparin Powder is also available in containers of 100 000 i.u.

## 'ESTIGYN'

(Ethinyl Oestradiol B.D.H.)

*An Orally Active Derivative  
of the Natural Oestrogen, Oestradiol*

Ethinyl oestradiol is unique in that it is a simple derivative of the natural ovarian hormone which is highly active when administered orally. It is now available for clinical use as 'Estigyn'.

'Estigyn' may be prescribed in all cases in which an oral oestrogen is indicated, especially those in which the physician hesitates to prescribe one of the synthetic, non steroid oestrogens.

Toxic reactions such as headache, nausea and vomiting, are rare following the administration of 'Estigyn' and are most unlikely after the usual therapeutic doses.

'Estigyn' is issued in tablets containing 0.05 mg., each tablet scored for convenience in giving doses of 0.025 mg. when these are required.

Literature is available on request.

The **NEW**  
penicillin suspension

Newest addition to the range of Glaxo penicillin preparations  
Procaine Penicillin G Oily Injection Glaxo offers significant  
advantages over the earlier oil-wax suspensions Each cc of  
the preparation contains 300 000 units of the procaine salt of  
penicillin in sterile suspension in arachis oil

**PROLONGED ACTION** Following a 1cc injection blood levels of  
penicillin are maintained for twenty four hours in the majority of cases  
**HIGH EFFICACY** Of the total procaine penicillin content not less than  
90 per cent by weight is present as the procaine salt of penicillin G  
**UNIFORMITY** Very little deposition of particles occurs during stor-  
age Shaking of the vial rapidly disperses the particles uniformly  
throughout the vehicle **MANAGEABILITY** Remains fluid at room  
temperatures refrigeration is unnecessary indeed undesirable  
Can be readily withdrawn from the vial without warming

of any at all, is the best method, and all, like Sir Paul, use such unfortunate expressions as "an almost complete freedom from undesirable complications for a long time". Similarly, of oxygen one is told "We see no need for it, our cases recover very rapidly, and we have no complications," or, "We always use it, we think it helps for this or that". For one make of 'box' it is even claimed that the type of fit produced is less likely to produce fractures than the fit from boxes working on another system.

There is much lip service paid in high places to the need for research in psychiatry, but surely the need for an inquiry into these simple points is more urgent and so easily undertaken. It is only necessary to take a series of alternate cases with and without restraint, recording not only the radiological injuries but the complaints of back-aches and to give alternate fits with and without oxygen, recording the depth and duration of cyanosis and the incidence of post-operation headaches and confusion, to settle these points. The claim that one make of 'box' produces a different type of fit, if taken seriously, could be settled by high speed cinematography.

If the value of oxygen should be established, can it be shown that there are any respiratory movements to justify its use before the end of the clonic phase? Oxygen may be cheap, but it has important industrial uses, and it seems wasteful to turn it on during the period of apnoea.

Similarly, if the need for restraint is established I question whether the 'Sutton' method described by Sir Paul is best suited to out-patient work. I have seen it used in two other clinics and think it is most alarming to the patient and wasteful of staff. I believe that whatever degree of restraint is required can be obtained by straps. Knowing the partiality of my Sutton friends to physiological theories I would point out that we are all positively conditioned to being strapped since our happy pram days. Anyone who has been taken aerobating knows how comforting are the hard tight straps that press one to the seat. But restraint by other people, particularly when gagged, is a highly provoking negative stimulus. Sir Paul says nothing about the use of pre-operative anaesthesia, to which I will refer later.

On the subject of selection of cases for out-patient treatment I find Sir Paul still more disappointing. It is already well known that the depressive patients are most likely to benefit, but every psychiatrist wants to know how he can usefully extend his range. What is the use of writing about "rigorous selection" and then quoting only two cases which from the details given come right outside the criteria and make spectacular recoveries? Are these the only occasions on which Sir Paul broke his own rules, or were there others with less happy consequences? Is there nothing more to say about the huskiness of the vocal cords except that she was resistant to psychotherapy and wanted to go abroad? She sounds like a Miss Penicillin wafted into the clinic on a breeze of urgency.

My final criticism is with the manner in which Sir Paul deals with the patients' reaction to the treatment. This, he writes, has been much over-emphasized. In actual fact from his own series five broke off because of their dread, ten ceased to attend (probably for the same reason) and 27 apparently became so bad that they had to be admitted during and after treatment. My estimate of the position is that not more than 5% of unanaesthetized patients are indifferent to the treatment, all the rest dislike it, 25% have to break off treatment because of their dread, and 50% have to summon all the courage they have not to be able to face it. Sir Paul does himself an injustice if he thinks that fearful patients are evidence of incorrect selection. I could show him one or two cases where treatment had to be broken off on account of the patient's dread but after some weeks was restarted at the same clinic and anaesthesia had been introduced and brought to a satisfactory conclusion.

Is it not possible that the line drawn across the affective disorders by ECT separating the depressive states from the manic states is an artifact? Other findings in psychiatry suggest that they are different manifestations of the same disorder depending on the personality of the sufferer. It may be that the manic states fail to respond because the techniques commonly employed are so desperately fear-provoking. My psychiatric clinic has its failed ECTs from other causes. Sometimes the patient has failed to attend, sometimes the patient has admitted having concealed their lack of progress, sometimes they could see of avoiding any more shocks, sometimes they offend the doctor. I hesitate to refer to my own results because the numbers are of no statistical significance. From the successes I have made are based chiefly on the fact that I have gained from it I would say that I give my

treatments single-handed, I use a home-made restraining device with webbing straps, I do not use oxygen, and I always use pentothal (about  $\frac{1}{4}$  of a 0.5 g ampoule, just sufficient to produce the first stage of relaxation). None of my patients has the slightest dread of treatment, some have failed to improve, but none have become worse—I am, etc.,

London NW 1

J F COOPER

## POINTS FROM LETTERS

### Tramatic Amputation

Dr CASSIA E WILLIAMS (Goring-by-Sea, Sussex) writes: Some years ago, while I was working in the North Midlands, a case of this kind was brought into the hospital during "Wakes Week". The patient was a stout, middle aged woman who had been riding on the roundabouts in a state of semi-intoxication. She failed to get off the platform when it stopped and was dragged round clinging by her left arm. This was completely avulsed at the shoulder-joint. There was hardly any bleeding, for the torn vessels were all twisted up, and the axilla looked quite clean. This patient died from shock before any attempt could be made to clean up the wound.

### Scratching in Bed

Dr D SAKLATVALA (Bournemouth) writes: I have tried several more or less clumsy arrangements to prevent a child with a rash from scratching in bed. The mother of one of my little patients has recently devised a neat and ingenious method which I believe is new. Each arm of the child is placed in a woman's stocking. The tops of the stockings are pinned together behind, between the child's shoulders, and the stocking feet are tied together. The child is perfectly controlled and very comfortable.

### Bilateral Stress Fracture of First Rib

Dr W E SNELL (Medical Superintendent, Colindale Hospital, London, NW 9) writes: At about the same date on which you published a report of a case of bilateral stress fracture of the first rib by Capt Roy Astley and Capt A Batty Shaw I observed a similar case in a theatre porter, aged 29, at this hospital. The x-ray shows a clear-cut line running through both 1st ribs in the region of the scalene tubercle, and the appearance almost resembles a joint. This porter has been lifting patients on and off trolleys and theatre tables for a period of two years, and this type of lifting may well involve sudden stresses on the first rib. Although he gives no history of pain, and no tenderness can be elicited on palpation, it seems that this must be another case of bilateral stress fracture.

### Failure of Kidney Function

Dr O S KOHNSTAMM (London, NW 2) writes: The following case shows, I think, some unique features. A man aged 68 was dying of cancer and secondaries (inoperable carcinoma of the pelvis of the left kidney). There was a probable involvement of the supra-renal glands. The patient had for some time refused solid food on account of severe nausea. On July 2 he ceased to pass urine, the bladder was empty. At the same time uraemic symptoms appeared. I gave 6 g NaCl and 10 g glucose in concentrated solution intravenously, which brought the patient round quickly. I told him to drink as much fluid as possible. Continuous drip proved unfeasible. On July 9 the patient passed  $1\frac{1}{2}$  oz (42.6 ml) of concentrated urine, which unfortunately could not be analysed properly. No urine appeared any more until the patient's death on July 18. Up to then the patient was comparatively clear and capable of making important decisions, at least at intervals. Blood urea was 240. All the time I had continued the concentrated injections, chiefly of glucose and salt solutions. The length of survival after the kidney had ceased to function and the clarity of mind are quite unusual. They may be connected with the lack of protein intake over a long period.

### The Common Cold

Dr G C PETHER (Hadley Wood, Herts) writes: Although much research has been done to determine the infecting agent in coryza I would suggest that one aspect of the matter has been neglected. Is it not possible that the defensive mechanism in the very front line—namely, the mucosa—could be considered with advantage? I have in mind that certain external agents, notably dusts, fumes, and extremes of heat and dryness, may reduce the defences considerably. The prophylaxis against catarrhal conditions is of great economic importance. For a time we are obliged to put up with scandalous travelling conditions, but it should be possible to discover whether the viruses of common catarrhs are helped or retarded by fumes of such substances as toluene, methyl alcohol and sundry other solvents. I do not think any statistical approach under factory conditions can give the answers. But proper laboratory experiments might be more promising than some which have been performed.

## Obituary

### RICHARD P STRONG, CB, MD

Emeritus Professor Richard P Strong who was professor of tropical medicine at Harvard University from 1913 to 1938 died in Boston, Massachusetts on July 4 at the age of 76. Strong was educated at Yale and Johns Hopkins, graduating MD in 1897. He entered the American Army Medical Service and soon attracted attention by his work on tropical pathology in the Government Laboratory at Manila. He became professor of tropical medicine in the University of the Philippines in 1907, leaving there on his appointment to the chair at Harvard in 1913. During the first world war, as Colonel Strong, he became well known to British physicians and pathologists in France, and the 'Report on Trench Fever' which he edited will be remembered by many. From 1917 to 1919 he served as a member of the Inter-Allied Sanitary Commission and in 1919 was made CB for his services to Britain.

Strong's work in tropical medicine took him to all parts of the world, civilized and uncivilized, and for his professional help to other countries besides his own he received many honours, he was either president of, or elected to, many learned societies. He was made an Honorary Fellow of the Royal Society of Tropical Medicine in 1936. He directed scientific expeditions to parts of the Amazon and in 1930 to the Belgian Congo and Liberia. His investigations in Amazonia foreshadowed the great Hylean Research Scheme which is now being inaugurated under the auspices of Unesco. Strong's two stout volumes on Liberia represent a wealth of scientific information and threw light on a corner of Africa which till then had remained in complete darkness. His most important scientific work, however, was carried out on onchocerciasis, which he had seen both in America and Africa; his investigations on this disease were embodied in a monograph published in 1934. He was head of so many commissions and committees that he was often away from his chair at Harvard, but all his efforts were everywhere and unremittently directed to one object—the improvement of medical conditions in the tropical countries throughout the world. Strong lived up to his name: he was tireless and of a robust constitution. It was characteristic of him that when America came into the war in 1942 he at once rejoined the American Army Medical Service although he had then turned 70. For four strenuous years he served at Army Headquarters, where his personal knowledge of the Tropics and subtropics was of inestimable value both to America and to the Allies. During this period he also found time to help in bringing out two editions of *Shill's Tropical Diseases*. He had a great capacity for friendship with those he liked and nothing pleased him more than to entertain his many friends not only in his home in Boston but in his many clubs, which were scattered throughout the principal cities of two continents. Many doctors in Britain, as well as those who knew him only by his work, will regret the passing of a sincere friend to this country and of a great servant of tropical medicine.

### P P COLE OBE, MB, FRCS

Mr R W Raven writes: May I add my tribute to the memory of the late Mr P P Cole (Oct 30 p 801)? We are conscious that a great personality has been removed from our midst and that we have lost a wise surgeon who contributed to our knowledge right to the end. He was an important master and his works have received the recognition which they merit. It is of interest to notice that the pathological investigations he made in 1913 concerning the intramural extension of carcinoma of the colon are quoted by the authors of a study of the same subject in the current number of *Surgery Gynecology and Obstetrics*. His was a mind which penetrated immediately into the essence of a surgical problem and was able to marshal the facts required for its solution. The scope of his surgical thinking was very wide and his experience in the art was commensurate but his real love was reparative surgery. At the Royal Cancer Hospital I often sought his advice when

planning a surgical procedure which would necessitate at some stage a reconstruction operation: he was always most helpful. P P Cole endeared himself to those who really knew him. Supremely honest and straightforward with no thought of self, his opinion regarding affairs was most valuable and was coloured by fine judgment and clear vision. We will remember him and all the little human touches which he brought into our daily lives. Who can forget that figure pacing up and down a room with head bent considering some problem, the sudden arrest and crisp 'Look here, liddle'. We cannot forget him, and the impact which he made on our lives will remain.

Surgeon-Captain Percival M May, R N, writes: As medical officer of the Royal Hospital School, Greenwich for some thirteen years, Mr Percival P Cole operated on many of the surgical cases that I had to send into the Drenthout Hospital. I often consulted him on cases that worried me, and I always found him ever kind and helpful. Many old boys of the R H S have much reason to thank Mr Cole for what he did for them. I often saw him operate and much admired his skill and dexterity especially in cases of facial deformity.

Mr E S Page writes: I should like to call attention to a point in surgical technique elaborated by my late lamented teacher, Mr Percival P Cole. I refer to the double pointed needle which had the eyelet situated in the middle of the shaft of the needle. Using the movements of pronation and supination of the wrist, stitches could be placed with accuracy, speed and precision that I have never seen surpassed once the manoeuvre had been mastered. Always a strong advocate of the 'no touch' technique, this needle enabled him to put into practice this admirable principle. Surgery has lost a great exponent in the passing of P P.

Dr L Carlyle Lyon writes: May I add a few words of personal appreciation to the tributes already paid to the late Percival P Cole? I had the privilege of working under him as house-surgeon at Queen Mary's Hospital for the East End in 1928 and the memory of his brilliant surgery, profound judgment, and not least his scintillating wit will remain with me for all time. His passing is a grievous loss to surgery as well as to his wide circle of friends and admirers.

Dr CECIL PRYOR LANKESTER died on Oct 13 at the age of 74 at his home in Peaslake, Surrey, where he had retired several years previously owing to failing health. Although coming of a medical family, his father and three brothers being members of the profession, his first inclination was towards law, but the urgent need for medical men in the missionary field craved him to throw up his legal studies and embark upon medicine. Immediately upon qualifying in 1897 he joined his brother at the CMS Hospital at Peshawar, and worked as a medical missionary in India for nine years. Then he returned home and entered general practice at Guildford. Shortly afterwards he became one of the medical officers to the Royal Surrey County Hospital and he continued with this work until he was compelled to give up because of his increasing deafness. Dr Lankester then took up radiology, and until failing health finally compelled him to retire, at the age of 64 he held the post of radiologist, and was subsequently in charge of the electrical and x-ray therapy department, at the hospital. Lankester was keenly interested in ambulance work and rendered valuable service in this field during the first world war. He was for many years honorary divisional surgeon to the local St John's Brigade, and during this time he gave regular classes in first-aid and nursing. For these services he was made an honorary associate of the Order of St John and assistant commissioner of the brigade in Surrey. When war broke out in 1939 his health prevented him taking an active part in ambulance work, but his energetic spirit and desire to do something would not allow him to rest and, as he was always keen on engineering, he occupied himself in making delicate machine parts on his private lathe at home. Lankester was an ardent evangelical churchman, keenly interested in mission work and the YMCA, and for eight years he was vicar's warden at St Saviour's Church. He was a member of the British Medical Association for thirty years and served on the Organization Committee from 1919 to 1922 and on the Insurance Acts Committee and the Organization of Medical Students Subcommittee from 1919 to 1921. He represented his constituency at the

annual Representative Meetings on six occasions and he was also honorary secretary of the Surrey Branch from 1922 to 1924 and chairman of the Guildford Division in 1924-5. Lankester will be remembered for his quiet, courteous, and unassuming manner, his devotion to religion, and his unbounded energy and desire to be of service even when in failing health. He leaves a widow and three sons, one of whom, Dr Lionel V A Lankester, is in practice at Guildford—A F T

Dr EDWARD AUGUSTUS BULLMORE died in London on Oct 29 at the age of 73. Dr Bullmore was born in Budock, Cornwall, in 1875 and educated at Falmouth School and at University College Hospital London. He qualified in 1898 and took the Edinburgh F.R.C.S. in 1903. He held several house appointments at his teaching hospital and was also house physician at the North Eastern Hospital for Children. Subsequently he was a ship surgeon with the P & O Line, and in the 1914-18 war he served with the R.A.M.C. Dr Bullmore had been a member of the British Medical Association for over forty years, and he was president of the Cambridgeshire and Huntingdonshire Branch in 1936-7.

Dr Max F Taylor writes: For the past thirty years I have only occasionally seen my old friend Dr E A Bullmore but for a decade or more previously I was in partnership with him and the late Dr Rupert Butterworth at Wisbech. Long ago as those days seem, their memory is still very green, and I recall with great happiness my association with him. He was a most loyal colleague and his outstanding sincerity and devotion to duty made him loved and trusted by all. Like many men of his stature he had a gentle voice. He had nothing petty in his disposition and spoke ill of no man. His professional ability was high; he always kept in touch with the advances of medical science and his good work will long be remembered in the district in which he spent practically his whole professional life. Besides his professional work he had many other interests, and had long looked forward to a greater enjoyment of these on his retirement to his native Cornwall. This, alas, was not to be, for owing to the war his retirement was delayed, he still worked on in practice and when at length he did retire the years he had left to him were sadly marred by frequent and serious illness, borne without complaint. He died not in his native county but in the hospital in which both he and his wife had served.

Dr ALEXANDER COWIE PATERSON died at Millbrook, Plymouth on Oct 22 at the age of 54. He was educated at Kemnay High School, Aberdeenshire and went on to Aberdeen University where he graduated M.B., Ch.B. in 1918. He joined the R.A.M.C. immediately and served for some time with the Army of Occupation in Germany. Towards the end of 1919 Dr Paterson entered the West African medical service and went out to the Gold Coast. He was appointed S.M.O. of Sierra Leone in 1929 and returned to the Gold Coast a year later. Early in 1938 he had to resign from the service on account of ill health and he then joined the staff of the Ministry of Pensions. After nearly three years at the Ministry he went into general practice at Millbrook and soon became well known as a painstaking and conscientious practitioner. The sympathy of his colleagues, his friends, and his many patients will be extended to his wife and his daughter.

Dr Alfred Cox writes: Your generous and well-deserved notice (Nov 6 p 839) to my old friend C H Milburn omits one of his activities of which he was justly proud. Always interested in the military side of medicine he was an active member of the B.M.A. committee whose report was largely responsible for the establishment of the R.A.M.C. fifty years ago. When I attended the jubilee celebration of the Corps I was not surprised to hear that Milburn's memory was remembered for the celebration. I had known Milburn to be a member of the Constitution Committee of 1900 and to be interested in the transformation of the Association into a more democratic body. I am now the only member who was hoping to live to take part in the 50th Anniversary Meeting next year and a recent letter to me from the Association of failure of his intellectual powers.

### HOUSE OF LORDS

#### Subscriptions to Hospitals

LORD SALTOUN in the House of Lords on Nov 2, asked whether the removal of hospital collecting boxes from railway stations was not contrary to the Government's expressed desire that private subscriptions to hospitals should continue.

LORD SHEPHERD, replying for the Government said the Minister of Health and the Secretary of State for Scotland hoped and were confident that private generosity, which had in the past done so much for the hospital service, would not come to an end. But they did not consider it proper that the new governing bodies of hospitals, which were public bodies no longer dependent on private charity, should themselves appeal for funds. Appeals made by independent voluntary organizations on behalf of the hospital service or of particular hospitals for money to provide extras and amenities outside the ordinary running of the service were a wholly different matter.

### HOUSE OF COMMONS

#### Payment of Specialists

SIR ERNEST GRAHAM-LITTLE asked whether Mr Bevan knew that many young consultants were undergoing severe financial privation owing to the delay in the payment of their remuneration for three months, during which time they had to pay interest on overdrafts at their banks, and whether he would take measures to prevent repetition of this delay.

Mr BEVAN replied on Nov 2 that certain Regional Hospital Boards were unable owing to initial staffing difficulties immediately after the appointed day, to pay specialists before the end of September. He saw no reason why this difficulty should continue. The Board which Sir Ernest had in mind were now paying monthly or quarterly at the wish of the specialist.

Mr HASTINGS asked the Minister of Health to give instructions to Regional Hospital Boards that advertisements for senior specialist staff should appear in the medical press and not in the lay press only.

Mr BEVAN replied that Regional Hospital Boards were required by Regulation 5 (1) of the National Health Service (Appointment of Specialists) Regulations, 1948 (S.I., 1948, No 1416) to advertise vacancies on the specialist staff of hospitals in two or more professional journals. He promised to inquire into any case where Mr Hastings believed that this regulation had not been followed.

#### Cost of N.H.S.

SIR STAFFORD CRIPPS stated on Nov 2 that the National Health Service and the National Insurance schemes would have been in force for the last nine months of the current financial year. He estimated that during this period the cost to the taxpayer of the former would be equivalent to an income tax of about 1s 0½d and that the contributions of the Exchequer to the latter would be equivalent to one of about 8½d.

#### Basic Salary

Mr RANKIN on Nov 4 asked why it had been decided that new entrants to the general practice of medicine were not to receive the basic salary as of right.

Mr BEVAN said this had been done to meet the wishes of the medical profession themselves.

Mr HASTINGS inquired in how many cases applications for basic salary had been received by executive councils in England and Wales, and in how many cases this had been granted.

Mr BEVAN replied that precise figures were not available but that more than a thousand applications had been granted. The matter was primarily for the executive councils, and unless appeals were made he did not receive the information at this stage.

Dr SEGAL asked whether Mr Bevan agreed that the attempt on the part of the medical profession to impose a means test on doctors who applied for a basic salary was an effort to defeat the whole object of the basic salary.

Mr BEVAN said it would be undesirable for him to make a comment on the representations of the medical profession. He must deal with its representatives. If doctors had individual complaints they should make them first to the profession so that he could hear them through the profession.

### Food poisoning

Mr CHARLES TAYLOR on Nov 4 asked Mr BEVAN to introduce legislation making it compulsory for handlers of food to be examined periodically to ascertain that they were not carriers of disease such as paratyphoid.

Mr BEVAN was afraid the very elaborate arrangements which would be needed were at present impracticable, and that the present state of knowledge would not justify them.

Mr ORBACH asked whether the Minister of Health in view of the number of cases of food poisoning recently reported, was satisfied that existing legislation and regulations were adequate to deal with the manufacture and sale of impure and unclean foods.

Mr BEVAN said that so far as this could be controlled by regulation there were already wide powers. Whether further practical measures could usefully be taken was engaging the attention of his Department in conjunction with the Ministry of Food.

Mr HASTINGS asked Mr BEVAN whether his attention had been called to the danger of the dissemination of typhoid fever, infantile paralysis, and other diseases as the result of the lavatories of main line trains discharging directly on to the track and what action he proposed to take.

Mr BEVAN replied that there was hardly any evidence at present that disease was spread in this way. His medical officers kept in close touch with current research in this field.

### Press at Committee Meetings

Mr BEVAN said the function of Hospital Management Committees was the day-to-day control and management of their hospitals. While he hoped they would take every opportunity of keeping the closest contact with public opinion, the admission of the Press to their meetings was a matter for their own decision.

### Controls Off

Mr WILSON on Nov 4 set out a long series of relaxations or modifications in Board of Trade controls. These included the relaxation from last June of administrative control of distribution of lactic acid, edible and B.P. and of calcium and sodium lactates, a similar relaxation, from October, of the control of potassium permanganate, and change from public to private purchase of pyrethrum. During November and December he proposed to revoke the statutory control of amyl-alcohol, carbonate of potash, dehydrated castor oil, methylated spirit and paraformaldehyde, and to abandon the permit scheme for distribution of vacuum flasks.

### Treatment in Switzerland

On Nov 4 Mr BEVAN told Mr Anthony Greenwood that he had no power to make it possible for regional boards to pay for the treatment of tuberculous cases in Switzerland. Mr Greenwood asserted that this had been the practice of some county and county borough councils before the National Health Service Act came into operation. Mr BEVAN said he had no power to authorize expenditure of that kind. He could not agree that patients were worse off than before the Act. If further forms of treatment could be given in other countries the remedy was not to send British patients there but to make that form of treatment available here. He did not accept that forms of treatment were available elsewhere which could not be provided here. It was undesirable that they should spend large sums of money in sending patients abroad. A committee working in conjunction with the Treasury considered whether hardship cases could be sent abroad. That was a matter for the Treasury and not for him.

Mr GREENWOOD said there was a serious shortage of beds for treating tuberculous cases and if some patients could be sent abroad it would be a relief.

Mr BEVAN replied that there was no serious shortage of beds. The most serious shortage was of staff. The Ministry was doing its best to recruit staff. It was far better at present to use its energies in that direction.

### Disseminated Sclerosis

Answering a question put on Nov 4 by Mr JANNER Mr HERBERT MORRISON said observations on cases of disseminated sclerosis were being made by neurologists in hospitals throughout the country in the hope of gaining a better understanding of its cause and nature or of improving its treatment. Investigations were in progress at the Radcliffe Infirmary, Oxford and at the Middlesex Hospital, London. Much research had been done in the past with Government aid and otherwise. Such aid had not been sought for either of the special investigations he had named but support would be forthcoming if required for exploiting any promising new idea on the subject.

One must be selective as to a promising line of research, but his Department was on the look out for it.

### Air Ambulances

Mr LINDGREN said on Nov 3 that it was necessary on occasion to remove patients by air ambulance at short notice from some Hebridean islands to hospitals on the mainland. Where ground facilities were available patients were so removed at all hours of the day and night. He would ask the Scottish Health Department to communicate with medical men in the Hebrides to make this information more widely known.

**Alien Doctors**—The number of medical practitioners enabled to practice in this country by virtue of registration in the foreign list of the *Medical Register* under the Medical Practitioners and Pharmacists Act, 1947 since Jan 1 last is 932 of whom all but 85 had previously been temporarily registered. The number of dental practitioners registered in the foreign list of the *Dentists Register* this year is 37.

**Joined Health Service**—Mr BEVAN told Mr CHETWYND on Nov 4 that 18,165 general practitioners and 8,343 dentists had joined the Health Service. The proportion of the population which had joined was 93.1%.

**Cars for Nurses**—The possibility of improving the supply of motor-cars for midwives and home nurses is being examined. Arrangements already exist for motor dealers to give preference to midwives.

**Streptomycin**—The Minister of Health is satisfied that there are sufficient supplies of streptomycin in the country to benefit all war casualties who require this treatment.

**Break down Denied**—About 1,750,000 persons have applied for free dental treatment since the setting up of the National Health Service. Mr BEVAN denied that doctors and dentists were breaking down under the strain put upon them by the Service.

## Medico-Legal

### SCHIZOPHRENIA AND RESPONSIBILITY

[FROM OUR MEDICO LEGAL CORRESPONDENT]

In the early morning of May 15 a night nurse at the Queens Park Hospital, Blackburn missed one of the children from her ward. Search was made at once and the little girl's body was found in a near-by field. She had been raped, and had been killed by having her head battered against a wall. Surprisingly, the murderer had left behind a set of finger prints on a bottle and the police matched these against no fewer than 46,000 prints taken from men known to have been in Blackburn on the night of May 14. The culprit was found to be a youth of 22 named Peter Griffiths. In a statement he made to the police he said that he had spent the evening drinking that a man he did not know had given him a lift in a car and dropped him outside the hospital that he had got over the railings and later found himself outside a ward where there were children. He took off his shoes and left them outside, tried the door which opened to his touch and went in, but heard a nurse at the sink and came out again. He re-entered the ward went into the kitchen and picked a bottle off a shelf at random, took it into the ward and left it on the floor. Thinking he heard a nurse he turned round lost his balance and woke up one of the children who started to cry. He hushed her, but another child woke so he took the first in his arms out into the field and put her on the grass. As she would not stop crying he lost his temper and swung her by the feet against a wall until she died. He went back into the hospital put his shoes on again and went back to where he had left the child and then to his home. He read about the murder in the paper next day but was not shaken and behaved normally until he was arrested. He expressed regret and sorrow for the child's parents and "hoped he got what he deserved."

At his trial at Lancaster Assizes before Mr Justice Oliver it appeared that he had spent two years at the hospital as a child of 8 and that a week before the murder he had heard that his half brother's daughter aged 24 years was in the hospital. His father had been confined in a mental hospital for nine

months in 1918 suffering from paranoid schizophrenia, and at the age of 6 he himself had fallen on his head out of a milk float. His disposition and habits were childish. A few days before the murder his girl friend had broken off their association.

Dr Alastair Robertson Grant, medical superintendent of Whittingham Mental Hospital, said that he regarded Griffiths as an early case of schizophrenia and considered that he had been suffering from the disease at the time of the murder. He thought that the prisoner had known what he was doing, but had not fully appreciated that he was doing wrong. In cross-examination he said that he considered that the mania began when Griffiths had started to attack the girl and had ended after her death. It was very common in cases of schizophrenia to have a blank in memory, but not invariable. He agreed that Griffiths's description of his movements in the hospital ward were those of a man, alert and conscious, who knew he was doing something he should not be doing. Griffiths might not have remembered committing the assault on the girl and that might have been the reason why he had not mentioned it in his statement.

The judge asked why he should forget that if he remembered everything else and the witness replied that that was the sort of partial amnesia that occurred in drink. In ordinary schizophrenia he would be rather surprised to find that a man had remembered so much and had forgotten such an important thing. It was quite possible for a schizophrenic to have a maniacal attack for a short time and then recover himself quickly afterwards with full knowledge of what had happened. Prosecuting counsel asked why from the prisoner's statement the witness had fixed the time of the maniacal attack at the time he had placed the child on the grass. The judge interposed to suggest that if the prisoner had been in a schizophrenic mania he would have dashed the girl down in the ward, and the witness replied, "Yes".

The police surgeon Dr Gilbert Bailey said in cross-examination by Griffiths's counsel that he considered that the man who did this act must have been in a state of maniacal frenzy, but that normally such a man could not be certified. He had formed the opinion that the man who committed the murder was a schizophrenic and agreed that a person suffering from that disease might suffer a defect of reason as a result of which he might not know at the time that what he was doing was wrong. Dr Francis Brisby, the principal medical officer at Liverpool prison, testified that from observation and examination he had found no evidence of any disease of the mind.

The judge said in his summing up that there was abundant evidence that this might have been the act of a lunatic and that Griffiths might have been a sufferer from schizophrenia, but the vital matter was: Did he know that what he was doing was wrong or did he not? After an absence of 23 minutes the jury found the prisoner guilty and the judge said that the jury had found him guilty of a crime of the most brutal kind and he entirely agreed with their verdict. He sentenced Griffiths to death in the traditional words, which since the introduction of the Criminal Justice Bill judges have usually replaced by the new shorter form.

### M'Naghten Rules

The rules of responsibility for a criminal act on the ground of insanity will be contained in the 'rules in M'Naghten's case' which were laid down over one hundred years ago by the judges of the House of Lords in the course of a trial but on the request of the House of Lords Chamber. In this the ruling is unique in the history of a valid legal principle. It lays down that in order to establish a defence on the ground of insanity it must be proved that at the time of committing the offence the accused was labouring under such a defect of reason as to be incapable of knowing the nature and quality of the act he was doing or if he did know it, that he knew that what he was doing was wrong. In the case of M'Naghten the defect of reason was the result of a disease of the mind and the act gave rise to strong evidence of insanity and he clearly had a defect of reason of mental instability. There was no doubt that he knew what he was doing and

that it was wrong. The defence of irresistible impulse is not open to a defendant in our courts if it had been his advisers would in all probability have made it their principal defence. This is a typical borderline case of the kind which raises again the question of whether the M'Naghten rules, so clearly anachronistic and out of line with modern knowledge of the mind and of responsibility, ought any longer to be tolerated. Their amazing persistence is due to several factors, but probably one of the most important is that in practice they work unexpectedly well and that in the few cases in which they would allow an irresponsible offender to be condemned the Home Secretary's exercise of the Royal Prerogative stands behind the court to prevent a miscarriage of justice.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

Edgar Douglas Adnan, O.M., M.D., F.R.C.P., F.R.S., Professor of Physiology in the University, has been appointed a Manager of the Piment-Darwin Fund for three years from Jan. 1, 1949, and Henry Albert Harris, M.D., Professor of Anatomy in the University, a Manager of the Charles Slater Fund for four years from Jan. 1, 1949.

The Faculty Board of Medicine has approved the courses in pharmacology given at the Middlesex Hospital, University College Hospital, and St. Mary's Hospital Medical Schools.

The Raymond Horton Smith Prize for 1947-8 has been awarded to Dr. David Vercel, of Corpus Christi College.

Professor Geoffrey Jefferson, F.R.S., will deliver a lecture on "Cerebral Compression in Man" in the Physiological Laboratory theatre of the University on Friday, Dec. 3, at 5 p.m. The lecture is open without fee to members of the University.

The following medical degrees were conferred on Oct. 16:

M.D.—O. C. Lloyd  
M.B., B.Chir.—H. Middleton \*J. Wedgwood \*N. R. Greville \*A. Hill  
\*I. C. Peebles

\*By proxy

### UNIVERSITY OF LONDON

The following awards have been made to students of the course for the Academic Diploma in Public Health at the London School of Hygiene and Tropical Medicine for the year 1947-8: *Chadwick Prize*, P. M. Elliott, *Hecht Prize*, G. Ladkin and N. S. Hepburn, *Industrial Medical Officer's Prize*, P. M. Elliott and D. F. Eastcott. The Duncan Medal in the course for the Diploma in Tropical Medicine and Hygiene (England) at the school for the year was awarded to Hing-Yui Mok.

The title of Professor Emeritus of Bacteriology in the University has been conferred on Sir Alexander Fleming, M.B., F.R.C.P., F.R.C.S., F.R.S., Professor of Bacteriology at St. Mary's Hospital Medical School since 1928.

The title of Professor Emeritus of Medicine in the University has been conferred on Sir Francis Fraser, M.D., F.R.C.P., Professor of Medicine and physician at St. Bartholomew's Hospital Medical College from 1920 to 1934 and Professor of Medicine at the British Postgraduate Medical School from 1934 to 1946.

Professor Robert Wilfred Scarff, M.B., B.S., has been appointed to the Bland Sutton Chair of Pathology tenable at the Middlesex Hospital Medical School, from Oct. 1.

### UNIVERSITY OF WALES

The following candidates for the degrees of M.B., B.Ch. at the Welsh National School of Medicine have satisfied the examiners at the examination indicated:

Honours—Marjorie J. Adams, Mary P. E. Alban, F. W. Beswick, C. H. Bannister, Maldwyn L. Cattell, R. B. Davies, Elizabeth B. Dew, D. C. Dymond, L. E. Elton, A. R. Evans, K. Gammon, P. H. Griffiths, E. J. Gwynne, G. E. Heard, J. J. Hocking, June D. James, Ruth E. Lewis, Mair G. Lloyd, D. P. Miles, Rhona E. Morgan, R. Buddug Phillips, H. M. N. Rees, J. A. E. Richards, R. M. Richards, \*D. C. Saunders, C. P. Seaser, \*J. A. Stanton, Brenda M. Thomas, D. G. H. Thomas, E. Thomas, J. G. H. Thomas, S. Thomas.

\*With distinction

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At the annual meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, held on Nov. 1, the following officers were elected: *President*, Dr. W. R. Snodgrass, *Visitor*, Mr. Walter W. Galbraith, *Honorary Treasurer*, Mr. Matthew White, *Honorary Librarian*, Dr. Archibald L. Goodall, *Representative on General Medical Council*, Mr. Andrew Allison.

## The Services

### TERRITORIAL DECORATION

The Efficiency Decoration of the Territorial Army has been conferred upon Colonel W. Graham, OBE, Major (Honorary Lieutenant Colonel) D. A. Langhorne, MBE, and Major A. G. Emslie, R.A.M.C., T.A.

Flight Lieutenant Alexander Mather, R.A.F.V.R., has been appointed MBE (Military Division) for distinguished service in Palestine.

### EPIDEMIOLOGICAL NOTES

#### Poliomyelitis in the British Zone

The peak of the outbreak of poliomyelitis in the British Zone of Germany was reached between Sept. 18 and 25, when 267 cases and 34 deaths were recorded. The following week a decline began, and this has continued. The total number of cases reported during September was 937 with 67 deaths almost double the figure for the previous month. Although the incidence has been higher this year than in September last year the mortality has been much lower. This is certainly due to better certification, and does not represent a true decreased mortality.

The 1948 British film on poliomyelitis, "dubbed" in German, has been shown in Hamburg and Berlin to large audiences of medical men.

#### Discussion of Table

In *England and Wales* an increase in the number of notifications was recorded for measles 767, whooping cough 214, diphtheria 12, and a decrease was reported for scarlet fever 130, acute pneumonia 53 and dysentery 15.

The largest rises in the notifications of measles were Lancashire 179, Lincolnshire 126 (mainly due to the appearance of an outbreak in Grimsby C.B., where the cases increased from 16 to 94), Yorkshire West Riding 69, Southampton 82, Gloucestershire 58. A small increase in the incidence of whooping cough was 43 in Cornwall. The notifications of diphtheria have increased by 27% during the past fortnight, during the week the largest rises were London 8, Devonshire 7, Middlesex 6 and the largest decrease was 9 in Warwickshire. The fall in the incidence of scarlet fever was confined to a few counties and the largest decreases in notifications were Essex 37, Lancashire 33, and Yorkshire West Riding 32.

Only one further case of typhoid fever was notified from Shropshire, Oswestry R.D. where during the past seven weeks 101 cases have been notified. This outbreak of typhoid occurred in the Orthopaedic Hospital. An outbreak of dysentery involving 22 persons was notified in Somerset, Bridgwater R.D. Only 7 further cases of dysentery were notified from Essex, Hornchurch U.D., where 50 cases were reported last week. In Lancashire a rise of 12 occurred in the notifications of dysentery. The largest returns of poliomyelitis were Lancashire 9 (Manchester C.B. 3), London 7, Kent 5, Surrey 5.

In *Scotland* a fall was recorded in the notifications of scarlet fever 47 and diphtheria 14, while a rise was reported for measles 26 and whooping-cough 12. There was a small increase in the notifications of scarlet fever in the cities of Edinburgh and Glasgow, elsewhere the incidence tended to diminish.

In *Eire* a decrease occurred in the notifications of scarlet fever 17, diarrhoea and enteritis 27 and measles 12, the only rise of any size was 30 for whooping cough. In Dublin C.B. the incidence of the common infectious diseases of childhood was unchanged. Notifications of diarrhoea and enteritis in Dublin C.B. were 17 fewer than in the preceding week.

In *Northern Ireland* the notifications of scarlet fever increased by 12 mainly owing to an outbreak involving 10 persons in Londonderry C.B. In Belfast C.B. the notifications of measles increased from 66 to 116.

#### Week Ending October 30

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,374, whooping-cough 2,060, diphtheria 129, measles 6,211, acute pneumonia 418, cerebrospinal fever 22, acute poliomyelitis 66, dysentery 68, paratyphoid 7 and typhoid 10.

### INFECTIOUS DISEASES AND VITAL STATISTICS

No 43

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct. 2.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths and of Deaths recorded under each infectious disease are far (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases, a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	31	5	17	3	1	34	1	19	—	1
Diphtheria Deaths	153	16	29	12	7	238	24	49	13	4
Dysentery Deaths	99	5	62	1	1	340	3	30	—	1
Encephalitis lethargica acute Deaths	1	—	—	—	—	—	—	2	—	—

Whooping-cough* Deaths	2,163	120	95	52	17	1,003	78	54	30	1
Deaths (0-1 years) Infant mortality rate (per 1,000 live births)	267	39	30	17	9	354	39	61	34	15
Deaths (excluding still births) Annual death rate (per 1,000 persons living)	4,371	710	534	158	104	4,364	729	578	177	93
Live births Annual rate per 1,000 persons living	7,270	1208	918	369	234	7,765	1290	1016	429	277
Stillbirths Rate per 1,000 total births (including stillborn)	193	24	25	—	—	254	32	24	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the figures are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales (London administrative county) will no longer be published.

‡ Includes primary form for England and Wales (London administrative county) and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales (London administrative county) are combined.

|| Includes puerperal fever for England and Wales and Eire.

## Medical News

### Information on Hospital Management

The King Edward's Hospital Fund for London has established a Division of Hospital Facilities comprising an information bureau, a library service, a library of hospital books, journals and plans and an index to hospital literature. The bureau will provide information on hospital organization and management to hospital officers, holders of bursaries, students of hospital administration, hospital committees and other organizations and individuals. Information may be obtained from the Director, Captain J. E. Stone, 10 Old Jewry, London E.C.2.

### Jacobaeus Memorial Lecture

In accordance with the statutes of the Professor Jacobaeus Memorial created by the Nordisk Insulin Foundation in 1939, a lecture is given every year under the auspices of the Memorial on some aspect of clinical or experimental medicine within the field of organology and endocrinology. Professor F. G. Young of University College London gave the lecture on Oct. 5 at the Rikshospitalet in Oslo the chair being taken by Professor Olav Hassnes. The subject of Professor Young's lecture was "The Relation of the Pituitary Gland to Diabetes Mellitus". The first Jacobaeus lecture was given by Professor Key in Sweden, and the second in Copenhagen in 1947 by Professor C. H. Best of Toronto.

### Industrial Rehabilitation

The Ministry of Labour and National Service announces that it is opening up 10 industrial rehabilitation centres in addition to three already opened at Birmingham, Coventry and Felling-on-Tyne "to help men and women who have got out of touch with working conditions through absences caused by sickness, accident, or by long unemployment an opportunity to become gradually accustomed to mental and physical exertions of a full day's work, and to regain the confidence to tackle a job, either of the kind which they were doing before they became disabled or of some other kind for which they are now more suited. For several years past a residential industrial rehabilitation centre has been in operation at Egham, in Surrey. The experiment has been so successful that some time ago the Ministry began to prepare for the establishment of six other centres on similar lines, but there is difficulty in obtaining suitable premises. The Ministry has therefore decided as an interim measure to use some of the accommodation which has become available at Government training centres as non-residential rehabilitation centres. The course at these new units will be broadly on the lines of the course given at the Egham centre, the objects being: (1) To give confidence and confidence persons who, although not in need of intensive medical treatment, are not fit for full time employment; (2) To cover by observation and tests and with medical advice the personal factors impeding satisfactory settlement in employment; and (3) To give guidance to placing-officers of the Ministry about the effect of a disability on a person's working capacity. The maximum length of the course will be 12 weeks, but in many cases it is expected that a month or six weeks will be sufficient. On completion of the course special efforts will be made to find the type of employment or training recommended by the placing-officer who has had the person under observation and to secure that the person will be eligible for allowances which are paid in the same way as the general scale for people undergoing training at a Government centre. The scheme is being issued to organizations in which industrial rehabilitation is being carried out. Another leaflet is being issued to employers in order to encourage applications for the

### Films on the "Neuraxis"

Owing to Professor Pedro Belou's inability to be in London on Nov. 15 to show his films on the Neuraxis, the meeting at the Royal Society of Medicine announced in Coming Events last week at page 844 has been cancelled.

### Food Hygiene Exhibition

Ilford Borough Council recently held an exhibition of "Food and Drink Infection Precautions". Photographs and diagrams illustrated how bacteria contaminate food, how the chain of infection may be broken by proper hygiene, and the methods adopted to suppress an outbreak of food poisoning. The medical officer of health, Dr. J. H. Weir, spoke at the exhibition.

### Dr. Robert J. Peters

Dr. Robert J. Peters, Deputy Chief Medical Officer, Department of Health for Scotland, sailed for the U.S. recently to attend the American Public Health Association's annual conference at Boston. He and Dr. A. H. Gale of the Ministry of Health, will attend a subcommittee on the control of infectious diseases set up by the Committee on Research and Standards of the American Public Health Association. Dr. Peters will conclude his U.S. tour with visits to Washington and to important centres of medical and public health education at Boston, Baltimore, and New York. He will return to Scotland at the beginning of December.

### Sir Thomas Houston

Sir Thomas Houston, consulting physician to the Royal Victoria Hospital, Belfast, and Pro-Chancellor of Queen's University, has been presented by his colleagues with his portrait in oils, painted by Mr. Frank M. Kelvey. The presentation was made by Professor W. W. D. Thomson, who referred to the affection in which Sir Thomas was held by the profession, his services to the community, and his work in bacteriology over the last fifty years.

### Mr. Clifford Ellis Roberts

The Sultan of Zanzibar has conferred the Order of the Brilliant Star of Zanzibar, Insignia of the Fourth Class, upon Clifford Ellis Roberts, OBE, BM, FRCS Ed, Specialist Officer, Health Department, Zanzibar, in recognition of valuable services rendered by him.

### Save the Children Fund

The Save the Children Fund announces that its hospital team is being withdrawn from the hospital at Schlutup, Schleswig-Holstein. The Fund has run this hospital of 100 beds since July, 1945, for the care of children from the neighbouring D.P. camps, and has also maintained a convalescent home in conjunction with the hospital. Local people were employed so far as possible and to an increasing extent, so that it might ultimately be transferred to the German authorities.

## COMING EVENTS

### London Medical Exhibition

The London Medical Exhibition will be held in the New Hall of the Royal Horticultural Society (Greycoat Street, Westminster, S.W.) from Monday, Nov. 15, to Friday, Nov. 19, from 11 a.m. to 6.30 p.m. each day.

### Empire Rheumatism Council

The autumn week-end course arranged by the Empire Rheumatism Council will be held at the Society of Apothecaries of London, Black Friars Lane, Queen Victoria Street, E.C.4, on Friday, Saturday, and Sunday, Nov. 26, 27, and 28. At 4.30 p.m. on Nov. 26 Dr. W. S. C. Copeman will open the course with "A Survey of the Rheumatic Diseases" and at 5.30 p.m. Dr. G. D. Kersley will discuss "Gout". The programme for the other two days is as follows: Nov. 27 10 a.m. Dr. F. Dudley Hart, "Spondylitis"; 11.15 a.m. Dr. W. S. Teener, "Rheumatoid Arthritis"; 2 p.m., Dr. R. E. Borham Carter, "Juvenile Rheumatism"; 3 p.m. Dr. Oswald Saage, "Fibrositis"; 4 p.m. Mr. J. H. Kellgren, "Differential Diagnosis of Backache"; Nov. 28 10 a.m. Dr. Hugh Burt, "Physical Medicine in the Rheumatic Diseases"; 11.15 a.m. Mr. W. D. Coltrant, "Orthopaedic Aspects of the Rheumatic Diseases". The fee for the course (limited to 100) is £2.2s. payable at least one week before to the general secretary of the Council at Tavistock House (North) Tavistock Square, London W.C.1.

### Course in Physical Medicine

A course in preparation for Part I of the Diploma in Physical Medicine will be held at Guy's Hospital commencing on Monday, Jan. 17, 1949, provided there are a sufficient number of candidates. Further information regarding this course can be obtained from the Dean of the Medical School, Guy's Hospital, London, S.E.1.

## SOCIETIES AND LECTURES

### Monday

HUNTERIAN SOCIETY—At Society of Apothecaries of London, Black Friars Lane Queen Victoria Street E.C., Nov 15 8.30 p.m. *That the Practice of Instructing the Layman in the Nature and Treatment of Disease is Being Carried to Excess* to be proposed by Dr W. J. O'Donovan and Miss Arnot Robertson and opposed by Dr Charles Hill and Miss Brown Lloyd-Williams

### Tuesday

INSTITUTE OF DERMATOLOGY 5 Lisle Street, Leicester Square, London W.C.—Nov 16, 5 p.m. *Histopathology of the Skin* by Dr I. Muende

INSTITUTE OF UROLOGY—At St Paul's Hospital, Endell Street, London W.C., Nov 16, 11 a.m., *Visceral Syphilis* by Dr E. G. B. Calvert at St Peter's Hospital, Henrietta Street, London, W.C., Nov 16, 5 p.m., *Aetiology Pathology and Symptoms of Benign Enlargement of the Prostate with Indications for Treatment* by Mr F. J. F. Barrington

LONDON UNIVERSITY—At Westminster Medical School Horseferry Road, London S.W., Nov 16 5 p.m. *Rubella in Pregnancy as an Aetiological Factor in Congenital Malformations and Still Births* special University Lecture by Dr Charles Swan (University of Adelaide)

SCOTTISH EASTERN ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION—At B.M.A. Scottish House 7 Drumsheugh Gardens, Edinburgh, Nov 16 8.45 p.m. *Recent Work on the Toxaemias of Pregnancy* by Professor R. J. Kellar

UNIVERSITY COLLEGE, Gower Street London W.C.—Nov 16 1.15 p.m. *Psychology as a Science—I* by Dr S. J. F. Philpott D.Sc.

### Wednesday

HARVEIAN SOCIETY OF LONDON—At 26 Portland Place, London, W. Nov 17, 8.15 p.m. *The Value of a Tumour Clinic in a General Hospital* by Professor Ian Aird

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square London, W.C.—Nov 17, 5 p.m. *X-ray Technique* by Dr C. W. McKenny

INSTITUTE OF UROLOGY—At St Paul's Hospital Endell Street London, W.C. Nov 17 11 a.m., *General Paralysis of the Insane* by Dr J. C. Hawksley at St Peter's Hospital, Henrietta Street, London, W.C., Nov 17, 5 p.m., *A Survey of the Different Methods of Treatment Available in Enlargement of the Prostate* by Mr R. Ogier Ward

ROYAL COLLEGE OF SURGEONS OF ENGLAND Lincoln's Inn Fields, London, W.C.—Nov 17 5 p.m. *The Portraiture of William Harvey* Thomas Vicary Lecture by Mr Geoffrey Keynes

ROYAL INSTITUTE OF PHILOSOPHY—At Eugenius Theatre, University College, Gower Street, London, W.C., Nov 17, 7.30 p.m. *State and Society* by W. H. Walsh M.A.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE 28 Portland Place London W.—Nov 17, 3.30 p.m. *Food—and Resistance to Disease* by Dr P. G. H. Gell

ROYAL MICROSCOPICAL SOCIETY—At B.M.A. House Tavistock Square, London W.C. Nov 17, 5.30 p.m. *The Royal Microscopical Society's Film Library* Aims and scope to be described by Dr A. F. W. Hughes

### Thursday

BRITISH INSTITUTE OF RADIOLOGY 32 Welbeck Street London, W.—Nov 18 8 p.m. *Angiocardiography as an Aid to Diagnosis of Cardiac Abnormalities* by Dr F. Gardner *Cardiac Anatomy as Demonstrated by Angiocardiography* by Dr J. M. Weston Wells

DREADNIGHT SEAMEN'S HOSPITAL Greenwich S.E.—Nov 18, 3 p.m. Clinical demonstration by Mr D. M. Cooper and Dr R. L. Mansi

EDINBURGH CLINICAL CLUB—At B.M.A. Scottish House 7, Drumsheugh Gardens Edinburgh, Nov 18 8 p.m. *Some Minor Orthopaedic Conditions* by Mr W. V. Anderson

EDINBURGH ROYAL INFIRMARY—Nov 18 5 p.m. *Blood Volume in Surgical Disorders* Honyman Gillespie Lecture by Professor W. C. Wilson

INSTITUTE OF UROLOGY—At St Paul's Hospital Endell Street London, W.C. Nov 18, 11 a.m., *Neurosyphilis* by Dr A. H. Harkness, 5 p.m., *Transvesical Operations on the Prostate* by Mr W. K. Irwin

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square London W.—Nov 18 5 p.m. Lloyd Roberts Lecture 'Victorian Doctor' by Mr J. Johnston Abraham

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN DARTFORD AND DISTRICT BRANCH—At Grammar School West Hill Dartford Nov 18 8 p.m. *d-Tubocurarine Chloride* Wellcome film, including *Sources and Isolation* by Dr T. Dewing Ph.D. *Standardization and Analytical Control* by Dr G. E. Foster Ph.D. and *Pharmacology* by Dr F. Prescott M.R.C.P. All members of B.M.A. and Royal Institute of Chemistry are invited to attend

ROYAL COLLEGE OF PHYSICIANS OF LONDON Pall Mall East S.W.—Nov 18 5 p.m. *Tuberculous Enlargement of Intrathoracic Lymph Nodes and its Aftermath* Mitchell Lecture by Dr Robert Coope

ROYAL MEDICAL SOCIETY—At Freemasons Hall George Street Edinburgh, Nov 18, 7.15 for 7.30 p.m. Presidents' annual dinner

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE—At School of Tropical Medicine, Pembroke Place, Liverpool, Nov 18 7.30 p.m. Laboratory meeting Various demonstrations will be given

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL Hyde Park Corner London, S.W.—Nov 18, 4.30 p.m. *Neurology and Psychiatry* Lecture demonstration by Dr Anthony Feilding

UNIVERSITY COLLEGE, Gower Street London, W.C.—Nov 18, 1.15 p.m. *Psychology as a Science—II* by Dr S. J. F. Philpott D.Sc.

### Friday

BRITISH TUBERCULOSIS ASSOCIATION—At Royal Empire Society Hall Northumberland Avenue, London, W.C. Nov 19, 3.30 p.m. *Tuberculosis—Some Statistical Problems* by Dr Percy Stocks *Radio sensitive Thoracic Tumours* by Professor B. W. Windeyer

FACULTY OF RADIOLOGISTS—At Royal College of Surgeons of England Lincoln's Inn Fields, London, W.C. Nov 19, 2.15 p.m. Diagnosis Section meeting, *Angiocardiography in Congenital Heart Disease* by Dr T. H. Hills

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY 330-2 Gray's Inn Road London W.C.—Nov 19, 4.30 p.m. *The End of an Era A Retrospect and a Prospect* annual address by Mr Walter Howarth

LONDON CHEST HOSPITAL, Victoria Park, E.—Nov 19, 5 p.m. *Asthma* by Dr J. R. B. Hern

ROYAL INSTITUTE OF PHILOSOPHY—At University Hall, 14, Gordon Square, London, W.C., Nov 19, 5.15 p.m. *Morality and Religion* by Dr Kenneth Kirk

ROYAL MEDICAL SOCIETY, 7, Melbourne Place Edinburgh—Nov 19, 8 p.m. *Medicine in the New Social Order* by Sir Francis Fraser

### Saturday

MIDDLESEX COUNTY MEDICAL SOCIETY—At Napsbury Hospital, near St Albans, Herts. Nov 20, 2.15 p.m. Meeting

## APPOINTMENTS

John Burke Ewing, M.D., C.M., F.R.C.S. Ed., F.R.C.S. Can., has been appointed Professor of Clinical Surgery at Ottawa University and Surgeon in Chief to Ottawa General Hospital

Mr Ewing is at present Surgeon to Wigan Royal Infirmary and is in charge of the surgical unit at Warrington General Hospital. He is a Canadian and qualified at Quebec University in 1932 obtaining the fellowship of the Edinburgh College of Surgeons in 1936 and of the Canadian College in 1937

DOWNER E. C., M.B. B.Ch. D.P.H. Medical Officer of Health for Barnsley  
JOHNSTON W. M.B. Ch.B. Assistant Medical Officer of Health for Derry  
O'BRIEN T. P. M.B. B.Ch. Assistant Medical Officer of Health for St Helens  
OVENS GERALD H. C. M.B. F.R.C.S. Professor of Clinical Surgery Farouk I University Alexandria Egypt

## BIRTHS, MARRIAGES, AND DEATHS

### BIRTH

Martin—On Oct. 18 1948 to Dr Audrey Martin (née Dealler) wife of Peter Martin 57 Narborough Road South Leicester a daughter

### MARRIAGES

McLaren—Evans—On Oct. 23 1948 in Edinburgh Donald Stewart McLaren M.B. Ch.B. Ed. to Olga Maiz Evans  
Pitchee—Smedley—On Oct. 30 1948 at St Mary's Church Crich Derbyshire Richard Kendall Pitchee M.C. M.R.C.S. L.R.C.P. D.O.M.S. to Elizabeth Margaret Smedley

### DEATHS

Ashe—On Oct. 26 1948 at Ryde House Northenden Road Sale Cheshire Charles Septimus Ashe M.B. Ch.B.  
Barton—On Oct. 26 1948 at 26 Willows Avenue Lytham St. Annes John Barton M.R.C.S. L.R.C.P.  
Bell—On Nov. 1 1948 James Adamson Bell M.R.C.S. L.R.C.P. of 11 Higher Tower Road Newquay Cornwall aged 81  
Bowie—On Oct. 29 1948 Margaret Campbell Bowie M.R.C.S. L.R.C.P.  
Brews—On Oct. 28 1948 at the London Hospital Richard Vincent Brews L.R.C.P. J.P. of 10 Pier Road North Woolwich E.  
Bullmore—On Oct. 29 1948 in London Edward Augustus Bullmore F.R.C.S. Ed. of 1 Florence Place Falmouth and of North Brink Withcham aged 73  
Cameron—On Oct. 25 1948 at Sheffield Donald Hugh Cameron M.B. Ch.B. D.P.M.  
Dudley—On Oct. 28 1948 at Caxton Cambs Edward Percy Hughes Dudley M.R.C.S. L.R.C.P. aged 74  
Huckett—On Oct. 31 1948 Alfred Edward Huckett M.B. Ch.B. Ed. of Lin. Road Doncaster  
Jeffares—On Oct. 26 1948 at Shanvalla Ramsey Isle of Man James Jeffares L.R.C.P. & S. Ed. L.R.F.P. & S. Glas. late of Kegworth Leicestershire aged 76  
Mackinnon—On Oct. 25 1948 at 43 Hamilton Terrace London N.W. Donald Mackinnon M.B. Ch.B.  
Milburn—On Oct. 27 1948 Charles Henry Milburn O.B.E. M.B. J.P. of South Drive Harrogate Yorkshire aged 88  
Mitchell—On Oct. 26 1948 at Bexhill Ernest John Drum Mitchell M.B. B.Ch.  
Strong—On July 4 1948 in Boston Mass Richard Pearson Strong C.B. M.D. Professor of Tropical Medicine Harvard University 1913 to 1938 aged 76  
Thomas—On Nov. 2 1948 at 1 Westend Lilian Mary Phillips Thomas M.R.C.S. L.R.C.P. aged 71

A new and distinct chemical compound issued in a tablet with a recently perfected enteric coating

- Brings Mandelic Acid Therapy up to date
- Potent and well tolerated
- Wide range of therapeutic activity
- No gastric upset dietary restrictions or fluid regulation
- Minimum accessory acidification
- Simple oral administration

**A woman with  
an intimate problem . .**

The question of whether or not to use internally worn sanitary protection is one which all women face sooner or later. In doing so, they naturally seek the guidance of one whose advice they completely trust—that of their Doctor. Tampax which was invented by a gynaecologist and has already been accepted by thousands of members of the Medical Profession throughout the world, deserves your endorsement for its assurance of hygiene, physical comfort and alleviation of mental strain. If you are not acquainted with Tampax, descriptive literature and samples of both absorbency sizes will gladly be sent on request.

\* Tampax may be confidently recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenal aperture would cause difficulty in insertion and withdrawal.

## 'GENATOSAN' DERMATOLOGICAL CREAMS

BACTERIOLOGICAL and extensive clinical tests have shown that a wide range of bacteriostatic and fungistatic agents possess enhanced effectiveness in 'Genatosan' water miscible ointment bases compared with the conventional greasy ointment bases. Advantages of 'Genatosan' Dermatological Creams include the following —

- 1 The medicament rapidly diffuses into the exudate and skin tissues
- 2 Heat radiation from the skin is unimpeded, thus avoiding irritation and discomfort
- 3 The cosmetic texture is not displeasing to the patient due to the vanishing cream base—thus ensuring conscientious use

### In the treatment of sprains

Strips of Paragon adhesive sponge rubber  $\frac{3}{4}$  in wide and  $2\frac{1}{2}$  in long, may be applied to the concavities on both sides of the tendo Achillis and curved round and beneath the malleoli.

An Elastoplast Bandage firmly applied over the resilient sponge rubber pads effectively relieves pain, controls swelling and prevents haematoma formation. The remarkable STRETCH and REGAIN properties of the woven fabric of Elastoplast, combined with the particular adhesive spread together provide the required degree of compression and grip.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Testing for Blood in Urine

**Q**—What is the best test for blood in urine? Please describe it in detail. Some laboratories use the pyramidon and others the guaiacum tests. Professor Sydney Smith in his *Forensic Medicine* (1945) recommends a solution of benzidine in glacial acetic acid and states that this solution keeps for long periods. I had a supply which changed to a port-wine colour after a few days. Will this affect the benzidine test?

**A**—There is no 'best' test for blood, but there are several excellent tests each useful under appropriate conditions. To detect haematuria, as in following the course of nephritis, it is essential to centrifuge the urine and examine the deposit with a microscope. Hand centrifuges can still be obtained, and a pocket microscope magnifying 200 to 300 diameters is quite satisfactory and costs only a few pounds. To detect haemoglobinuria, on the other hand, it is best to use a hand spectroscope.

The chemical tests are convenient and require no special apparatus, so for that reason they are still used in domiciliary practice, but they are many times less sensitive than microscopical examination and sometimes give false positives. If it is possible to perform a microscopical examination therefore, the chemical tests should not be used, the writer uses them so rarely that he does not keep any of the reagents made up. The benzidine test is about ten times more sensitive than any others, but it gives false positives with pus and iodides and with slight traces of dirt in tubes, so that it cannot be recommended. The pyramidon and guaiac tests are much less sensitive and give false positives only with iodides. The reduced phenolphthalein test is slightly more sensitive than the last two and gives few false positives. For these reasons the writer prefers the last, but uses the other two almost as frequently because they are much more convenient. Details of all three are therefore given.

**Guaiac Test**—Ozone ether, and an alcoholic solution of guaiacum resin prepared at the time of test by shaking a knife point of the resin with 2 to 3 ml of industrial spirit 74% over proof, are required. To 2 to 3 ml of urine is added 2 to 3 drops of the guaiac solution, after mixing, 15 to 20 drops of ozone ether are allowed to fall in and the tube is left to stand for a couple of minutes. A blue ring at the junction of the two liquids indicates blood or iodides. It is most important to use a freshly prepared solution of the resin, after a few days it becomes much less sensitive.

**Pyramidon Test**—Test the urine with litmus paper, and if alkaline render it just acid with acetic acid. Add 1 drop of glacial, or the equivalent of dilute acetic acid to 3 ml of neutral or acid urine in a clean tube, and pour an equal volume of the imidopyrine solution gently down the side of the tube so that it forms a layer above the urine. Holding the tube vertical, allow 5 to 10 drops of 10-volume hydrogen peroxide to fall into it from a height of 6 to 8 in (15 to 20 cm). A blue colour at the junction of the solutions indicates the presence of blood or iodides.

**Reduced Phenolphthalein Test**—The Kastle Meyer reagent used is prepared by dissolving 2 g of phenolphthalein and 20 g of caustic potash in distilled water and boiling with 10 g of zinc dust till the red colour disappears. After cooling, the solution is filtered and a few granules of the zinc dust are added to the filtrate to keep it reduced. This dust should settle to the bottom if it does not, the solution must be filtered before use. To 2 to 3 ml of reagent add 10 drops of hydrogen peroxide and 2 to 3 ml of urine and shake. A red colour indicates blood. The reagent keeps moderately well, though becoming less sensitive. Should it become pink, it can be regenerated by adding a small quantity of zinc dust and boiling.

The writer has never kept benzidine dissolved in glacial acetic acid and always prepares his own solutions from the components at the time of test. It is probable that old, coloured solutions are less sensitive than are fresh solutions though they will still work.

### Are Twins Sterile?

**Q**—There is a widespread idea in this area that if twins are of different sexes they are sterile. I had not heard this theory until a girl put it forward to 'prove' she could not be pregnant. The local veterinary surgeon claims that in twin pregnancies in cattle if the offspring are of different sexes they will be sterile if they have a common placenta. Can you comment on this?

**A**—In twin pregnancies in cattle anastomosis of the foetal circulations occurs seven times out of eight. Should the twin pair be of opposite sex the male hormones circulating in the female pervert the course of its differentiation, leading to a pseudo-intersex, which is sterile. The abnormality is not usually noticeable externally, so what has been observed by many generations of cattle-breeders is that a female born co-twin to a male is sterile seven times out of eight. The abnormal females are called free martins. Of course there is no such mechanism in the human species, yet the occurrence of the phenomenon in cattle is responsible for a highly persistent superstition in regard to man—a superstition that one would have imagined was clearly disproved within the experience of almost everyone.

### Penicillin in the Tropics

**Q**—What is the rate of deterioration of penicillin in the Tropics? Consignments here are exposed to temperatures averaging 80° F (26.6° C) and often running up to 100° F (37.8° C) for part of the day for periods of from five days to three weeks. East African suppliers used to deliver in large vacuum containers, but they now send by parcel post and state that penicillin retains its stability without refrigeration up to the date of expiry in normal storage. Is this correct?

**A**—Penicillin of present-day purity will withstand the conditions described if kept perfectly dry. There need therefore be no anxiety about oil-wax suspensions (one of the most stable of all preparations, because moisture cannot penetrate it), or about powder in sealed tubes, or tablets and lozenges in unopened tubes with waxed corks. Creams, on the other hand, will retain their potency for any length of time only in a refrigerator, and could certainly not be relied on after even one week of tropical heat.

### Cold Feet in Diabetes

**Q**—What is the cause of cold feet in a patient with diabetes mellitus?

**A**—If the complaint of cold feet is recent, atheroma of the arteries to the feet has developed. The diagnosis can be confirmed by feeling for pulsation in the dorsalis pedis and posterior tibial arteries, or by means of an oscillogram if the arteries cannot be felt. Treatment consists in keeping the feet warm by thick socks, or two pairs of well-fitting thin socks or stockings, the boots or shoes should be big enough to take the thick socks in comfort. Tight garters should not be worn. One or two pairs of loose bedsocks should be worn at night. Hot-water bottles should not be used and the patient should not warm his feet in front of a fire. Gentle exercise and massage are useful.

### Baker's Dermatitis

**Q**—What treatment do you recommend for baker's dermatitis? What is your opinion of the use of barrier creams in this connexion?

**A**—The causes of baker's dermatitis vary widely in different cases, and treatment depends on the cause. On the one hand the major factor may be the physiological instability of the skin in an eczema-prone subject, and at the other extreme the cause may be a specific allergic sensitiveness to one particular contact, such as a bleaching agent. The majority of cases arising in those who have been engaged in the trade for some years depend on the repeated injury occasioned by the sticking of dough to the skin and its removal. Barrier creams alone will rarely solve the problem, but where the dermatitis is due to sensitiveness to one or more particular ingredients they may

help provided contact with the agent is reduced to a minimum. Psychological factors often play an important part in the aetiology of industrial dermatoses.

### Transmissibility of Syphilis

**Q**—*In a family of five the father has sero-positive syphilis and is undergoing treatment the eldest child (8 years) has interstitial keratitis joint changes and is sero positive. The mother has not had any treatment and yet is sero negative (three Wassermann and Kahn tests at monthly intervals), and is without clinical evidence of syphilis other than the fact that she gave birth to a congenital syphilitic child. The two youngest children (4 and 2 years) are without clinical evidence of syphilis and are sero negative (three monthly Wassermann and Kahn tests). What treatment (if any) and what follow-up are recommended for the mother and the two apparently healthy children?*

**A**—This is not an uncommon story. It seems certain that the mother had syphilis and communicated it to the eldest child, but as her infection grew older the chances of communicating it decreased and the youngest children apparently escaped, the interval between the births of the first and second child (4 years) might account for this. It is well known that the transmissibility of syphilis decreases with the passage of time and serum reactions sometimes tend to reverse from positive to negative in the absence of treatment. No treatment is indicated for the mother and two youngest children at present, but periodical clinical examinations and serum tests would be a wise precaution, should the mother become pregnant again, treatment would ensure the birth of a non syphilitic baby. It might be advisable to examine the mother's cerebrospinal fluid to exclude the possibility of asymptomatic neurosyphilis.

### Cerebral Diplegia in a Child

**Q**—*How should one treat cerebral diplegia in a child aged 2 years? She is developing a number of athetoid movements and has occasional convulsions.*

**A**—Before planning the treatment it would be advisable in this case to know the extent of co operation of the child. Often these children have a normal mental capacity but are backward because of their physical defect. The attitude of the parents and the possibility of additional training in the home are also important facts to assess. If both are satisfactory, then it is advisable to start treatment in a physiotherapy department where the mother can watch and gain instruction on management in the home. The treatment of athetosis consists essentially in teaching the child to relax his muscles voluntarily and when this aim has been attained in re education in movement. If the home conditions are poor and the parents uncooperative it may be advisable to arrange treatment at a special residential home later. The treatment of the convulsions is the same as for epilepsy.

### Night Terrors

**Q**—*A girl 3½ years old began having night terrors eight months ago. Within a few weeks they became severe and occurred almost nightly. Attempts to prevent them were unsuccessful until it was noticed that when she slept in the afternoon there was no terror that night. She had been accustomed to sleep in the afternoons but the habit had lapsed with a little difficulty it has been regained and night terrors have almost ceased. They occur now very mildly about once a fortnight and then only when she has not slept in the afternoon. She is otherwise well. She has a sister of 9 months but no jealousy had been apparent until the last month since when she has become rather unamiable and a little negative and occasionally seems to resent the baby. Are the terrors due simply to over-fatigue or is there some underlying physical or psychological cause which shows itself in this way only when she is overtired? What can be done to eliminate them entirely?*

**A**—Any disturbing change in the family situation, such as the birth of another child in this case, tends to evoke night terrors during the fourth year of life which usually cease as the new situation becomes accepted. Until this solution is reached increased emotional tension induces physical fatigue which in its turn leads to disturbance of sleep. This cycle of events is clear with this little girl, who repressed all natural

jealousy of her younger sister and whose night terrors ceased when she slept during the day. As she is now showing openly her fear that the baby may absorb all her mother's love she will be able to get reassurance from being given some extra warmth of attention and the outlook is favourable. The afternoon rest should be continued as long as possible. If she is not already at a nursery school it would be well to consider this, so that she may gain confidence through social contacts and the acquiring of skills with others of her own age and in this way become less dependent on the mother-child relationship. If she goes to a nursery during the day, no doubt her mother will make a pleasant fuss of her when she returns in the afternoons so that she will not feel in any sense cast out because of the baby.

### Torn Tympanum

**Q**—*What is the usual rate of healing of an ear drum following traumatic rupture no infection being apparent? The tear which occurred three weeks ago is considerable, nearly a quarter of the infra posterior area being missing. There is no apparent damage to the ossicles. Beyond "rolling of the edges" the tear shows little true healing.*

**A**—A large tear may never heal, or the margin may become adherent to the promontory. Probably this tear will take some months to repair, provided infection does not supervene.

## NOTES AND COMMENTS

**Treatment of "Tennis Elbow"**—Dr J R ROSSON (Edgware, Middlesex) writes: Having had nine successful cases of "tennis elbow" this season I would like to add one or two comments to the reply under "Any Questions?" (Oct 9, p 699). In my experience physiotherapy is not only useless but in some cases aggravates the symptoms. The above cases had an injection of local anaesthetic in the point of maximum tenderness, followed by vigorous massage for about five minutes. They were then sent on to the courts for about an hour and were able to execute all movements without pain. I consider this last point of the utmost importance, as the patient is able to carry out all strokes without concentrating on any particular one. There was a mild local reaction the same evening which quickly responded to tab codain eo and heat. After four or five days they were able to resume normal play. Three other points are worthy of mention: (1) a large "grip" is desirable, thus diminishing the tension on the forearm muscles, (2) the body and shoulder should be brought into play rather than the elbow and wrist, (3) it is important to follow through at all times.

**Insurance Against Sickness**—The London Association for Hospital Services runs a non profit making scheme, which was initiated by the King Edward's Hospital Fund in collaboration with the hospitals and the B.M.A., to enable provision to be made for the expenses of medical and surgical treatment in hospital private wards or nursing homes. The benefits available under the maximum schemes approximate to the hospital charges and fees specified by the Ministry of Health in the regulations on pay bed accommodation. The London Association is sending a pamphlet outlining the scheme to members of the medical profession, and further particulars may be obtained from it at Tavistock House South, Tavistock Square, London, W.C.1.

**Recurrent Parotitis**—Professor R S ILLINGWORTH (Sheffield) writes: In reply to the question concerning recurrent parotitis (Oct 23 p 767), I did not feel that your answer was entirely satisfactory. Many of these cases are due to *St. viridans* or to the pneumococcus and these organisms may be recovered from the duct. In one child whom I have under treatment at present and who has had eighteen to twenty attacks in all I have found that prophylactic sulphur mezzathine (0.5 g per day) completely prevents the attacks. When I stopped the drug the attacks recurred. Penicillin lozenges did not prevent the attacks. The white cell count is done every fortnight.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 13 1948

## National Health Service

### APPEALS FOR BASIC SALARY

#### THE MINISTER DECIDES

The Minister has circulated to executive councils, "for their information and for their assistance in considering future applications," a memorandum setting out the factors considered by him when he recently allowed appeals against decisions of executive councils not to grant applications for the fixed annual payment of £300. Two such cases are described, and the facts, as summarized by the Ministry, are as follows:

(1) Two partners set up in practice in a small seaside town on June 1, 1948. In appealing against the decision to withhold the fixed annual payment they said they had relied on the statement in the Ministry's Memorandum on doctors' remuneration that new entrants to general practice would get a fixed annual payment for the first three years, and they could not continue in practice without the payment. There were 300 patients on their combined lists at the beginning of September.

The executive council and the local medical committee (whose comments on the appeal were invited) contended that there were already enough doctors in the area before the new practice was started, and that the area could not provide a competence for two extra doctors.

In allowing the appeal, the Minister took account of the following factors: (a) The doctors had just started a new practice and would suffer hardship without the £300. (b) The number of doctors in the area is a factor to be taken into account in considering applications made after July 5, 1948, to be placed on the medical list but ought not to affect the granting of the £300.

The appeal was allowed subject to the condition that within such period as may be specified by the Distribution Scheme (when that is available) the doctors have on their lists the minimum number of patients specified by that scheme, and on the understanding that the position will be reviewed annually.

(2) The younger of two doctors was taken into partnership in a different small seaside town in April, 1948. Both doctors applied for the £300. In appealing against the decision of the executive council not to grant the £300, the doctors explained that before July 5 the practice was mainly private and there was adequate income for both partners. There are now 900 NHS patients on the partnership list, with few private patients. There had been a considerable decrease in the income of the practice and it was impossible to continue in practice without the £300 fixed annual payment.

The executive council and local medical committee considered that, as the practice had originally been a one-doctor practice, the younger doctor could be regarded as undergoing a period of introduction with a view to succeeding to the practice, and that there was no question of hardship if the practice was regarded as a single-doctor practice.

In allowing the appeal the Minister took the following factors into consideration: (a) According to the information submitted by the doctors, which had not been contested, there had been a substantial drop in the income of the practice which was involving hardship to both doctors. (b) It seemed reasonable that for a period the younger doctor should have the benefit of the guidance of the elder, and, as in case (1) above, the fact that there were two doctors in the district where previously there had been one did not affect the granting of the £300.

The appeal was allowed on condition that the position was reviewed in a year's time.

If the considerations by which the Minister has been guided in allowing these appeals are to be accepted as the criteria on

which outstanding future applications will be dealt with by local executive bodies, the Minister's proposals for controlling the distribution of the profession—which are already leading to complications in more than one quarter—will become almost farcical. When the profession argued that the elaborate distribution machinery (which includes the Medical Practices Committee, with its invidious task of making a selection where there are more applicants than vacancies) was unnecessary in a 100% or almost a 100% service, the Minister's stock reply was that public money cannot be attracted to practice in areas where the public interest does not warrant it. When the profession demanded that practitioners should enjoy the elementary right to practise in the areas of their choice, his answer was that "this is a question of giving them the right to demand publicly remunerated work where they like—a position which no other profession or occupation enjoys."

#### Subsidy to Practise Where not Needed

Consider these utterances in the light of the facts set out above. Two practitioners established themselves a few weeks before the appointed day in a seaside area in which the local executive council thought there were already sufficient doctors and which "could not provide a reasonable competence for two extra doctors." The effect of the Minister's decision is that these practitioners jointly will receive £600 in basic salaries, and capitation fees for 300 patients reduced by one-seventh. This is some £831, or the equivalent of a capitation fee of 55s for their Health Service patients. The Minister has on more than one occasion sought to justify the basic salary "as an assurance for the young beginner and for the older practitioner wishing to ease up in old age, and as a peg on which to hang additional assured payments in doubtful areas." But in a service the cost of which is already some millions beyond the original estimates, and which provides in addition to ordinary remuneration a special inducement fund of £400,000 a year to attract medical men to "under-doctored" areas, it is difficult to appreciate on what hypothesis the Minister authorizes payments from public funds to two practitioners in an area where they are not needed for the public service, and at a rate over three times what their colleagues are receiving in the same and other areas.

Before the days of the National Health Service practitioners who found themselves in the position of the appellants would naturally have transferred to areas where the doctor-population ratio would have given at least a reasonable prospect of earning a living. It is remarkable that a Minister who doubted whether the introduction of a comprehensive service would by itself result in a more even distribution of the profession, and who because of those doubts has introduced elaborate administrative machinery to enable him to discharge his responsibility of securing a reasonable distribution, should within a few months of the inception of the Service subsidize practitioners at the public expense—and at the expense of the other practitioners in the area—to practise in an area where they are not needed.

## THE AMENDING BILL TO BE INTRODUCED THIS SESSION

The Amending Bill promised by the Minister of Health is expected to be introduced during the present session of Parliament. Mr Hugh Linstead has put down a Question asking the Minister whether he has received the report of the Legal Committee on Partnerships, what action he proposes to take on that report and, if legislation is needed when it is likely to be introduced. The Minister has agreed that the Bill shall include the following provisions: clarification of the position of partnerships in the light of the Legal Committee's report and that this clarification shall be made to operate retrospectively to July 5, a provision that a whole time salaried general medical service and also a universal full time consultant service, shall not be introduced by regulations—i.e., would need a further Act of Parliament, a provision that executive councils shall have the right to elect their own chairmen after the term of office of the present chairmen expires next March, and a provision to enable the professional member of the Tribunal to be one of a panel of available members and not a fixed individual (see Letter from Ministry, *Supplement*, June 5 p 155).

On April 8 Mr Bevan announced in Parliament the appointment of the Legal Committee on Partnerships with Mr (now Mr Justice) G O Slade K.C., as chairman, and Mr Colin Pearson, Sir Cyril Radcliffe K.C., Mr J H Stamp, and Mr J R Philip, K.C. (of the Scottish Bar), as members. The committee's report is doubtless now in the hands of the Minister, or soon will be, so the introduction of the Amending Bill should not be delayed much longer.

The General Practice Subcommittee of the Negotiating Committee submitted a memorandum to the Legal Committee on Partnerships. Its proposals were listed in the Appendix to the report of the Insurance Acts Committee (*Supplement* Oct 16, p 138). They include the important point that a partner who did not join the Service by the appointed day because of doubt about his position should have the right to join after July 5 if he wishes to do so in the light of the Amending Act, and that compensation shall be payable with retrospective effect from July 5.

The subcommittee has also pressed for the provision of drugs and appliances through the National Health Service for private patients, and has taken up the question of foreign visitors being treated under the N.H.S. without payment while in Britain.

## CONSULTANTS AND SPECIALISTS NEGOTIATIONS WITH THE MINISTRY

At a recent meeting with the Secretary, the Chief Medical Officer, and other senior officials of the Ministry of Health a deputation from the Negotiating Committee led by Lord Webb-Johnson raised a number of points in the hospital and specialist field.

The deputation drew attention to the hardship caused by the maximum imposed on interim payments to part-time specialists and asked that the discretion recently granted to the boards to raise the maximum in certain cases should extend to specialists doing less than the maximum of eight half-days a week. The Ministry promised to examine this suggestion. Lord Webb-Johnson described the serious financial position of many housemen. A house-surgeon whose salary is £10 a month (£120 p.a.) now sacrifices £1 a month in National Insurance contributions and £1 2s a month in superannuation contributions. This cuts his salary by 21% and leaves him with £7 18s a month, out of which he must clothe himself, provide himself with instruments and textbooks, pay his subscription to a medical defence society, and pay examination fees. Some of these young men are trying to support families. The Ministry stated that the answer to this problem was the early introduction of the new scales of remuneration, but if this was likely to be long delayed they would consider some immediate relief for these young practitioners.

The deputation put forward detailed figures to prove that the car mileage allowances for specialists are far from adequate to cover the costs of the journey and, of course, take no account

of the time spent in travelling. Similar representations were made as long ago as July. It is hoped that the case now presented will receive the Ministry's serious attention.

## Goodwill of Specialists' Practices

Lord Webb-Johnson again drew attention to the hardship caused in certain cases by the almost total loss of goodwill of specialist practices. The Ministry stated that it could not agree to pay compensation to these specialists, but reiterated its previous offer, in appropriate cases, to purchase equipment no longer required by specialists (a notice on this subject appears at p 173).

The attention of the Ministry was again drawn to the dislike of specialists for the quarterly maximum imposed on the payment for domiciliary visiting. The Ministry suggested that there might ultimately be a retrospective adjustment of this matter, and they advised specialists to keep a careful record of all domiciliary visits.

A number of other matters were discussed and are to be considered by the Ministry.

## SPECIALISTS' MILEAGE ALLOWANCE INADEQUATE

### COMPARISON WITH RUNNING COSTS

The inadequacy of the Government's mileage allowance paid to consultants and specialists—6d a mile for the first 2,880 miles, and then 3d a mile—was referred to in these columns last week (p 161) and was taken up with the Ministry on Nov 2 (see above). As many specialists have found from their own experience, the figures do not cover the costs of running a car to day. The B.M.A. sought the opinion of the Automobile Association on running costs, and the A.A. kindly provided some information relating to the years 1947-8 which they had prepared for the guidance of their members. The figures are approximate, but they show that a 10 h.p. car doing 5,000 miles a year costs on an average 695d a mile to run (including depreciation), doing 10,000 miles, it costs 445d. Most specialists have larger cars than this, however, and a 20 h.p. car doing 5,000 miles a year costs about 1348d a mile (10,000 miles, 808d). Other figures are in proportion.

## SPECIALISTS' £1,600 "CEILING" A MINISTRY CONCESSION

Last week reference was made to the hardship sometimes caused by the temporary £1,600 "ceiling" on the remuneration of part-time specialists. This point has now been admitted by the Ministry of Health, which announces a concession. The "ceiling" of £1,600 p.a. (apart from any remuneration derived from domiciliary visiting) is a temporary provision, subject to revision in accordance with scales of remuneration which will be drawn up after discussion with the profession in the light of the recommendations of the Spens Committee. But where it is clear that a specialist's remuneration will on adjustment be substantially more than £1,600 for the work which he performs for the board, and where the temporary limitation to £1,600 p.a. may meanwhile involve him in financial hardship, he may ask the regional hospital board or board of governors concerned for an increase in the interim payment.

This concession goes some way towards improving the position, but it does not cover the specialist who is undertaking less than eight sessions. Further representations on this point are accordingly being made.

## MATERNITY MEDICAL SERVICES A MINISTRY VIEW NOT ACCEPTED

What is the position of a doctor called in to attend a miscarriage, no previous arrangement for maternity medical services having been made between the patient and the doctor? The Ministry of Health states that if the patient is on the doctor's own list, a service of this character would come within his ordinary obligations as a general practitioner.

The Ministry adds that if the patient was on another doctor's list he would have no responsibility, unless he were called in when the patient's doctor and his deputy were not available, in which case the emergency arrangements would apply.

The Ministry's view is not accepted, and the matter is down for discussion at an early date.

## PETROL COUPONS

The N and L standard ration coupons, issued in June of this year, are valid for the month marked on them and also for the five succeeding months. For example, while coupons marked 'first month' will cease to be valid after Nov 30 next, those marked 'sixth month' will be valid until April 30, 1949. Similar conditions will apply to the new books valid from Dec 1, 1948.

## COMMITTEE ON REGISTRATION OF OPTICIANS ONE COMMITTEE OR TWO?

The Minister of Health and the Secretary of State for Scotland have decided to set up a committee to consider whether it would be to the public advantage to provide by legislation for the registration of opticians, and, if so, how registration should best be carried out and what qualifications should be required as a condition of registration.

The Ophthalmic Group Committee discussed the matter and thought there were two questions involved: (1) the principle of registration, and (2) how registration should be effected. The committee considers that the former question should be decided first, and has told the Ministry that the members of the single proposed committee might not necessarily be appropriate to the two subjects. It is suggested that the whole subject should first be investigated in general and that the committee to do this should include representatives of the interested parties—medical, optician, and general public. The Faculty of Ophthalmologists and the Royal College of Surgeons have also made the same recommendation to the Ministry.

## STATE MEDICAL SERVICE IN NEW ZEALAND RECOMMENDED ALTERATIONS

Ten years ago a Social Security Act was passed in New Zealand which introduced a system of general and specialist medical service for the whole community. Certain features of the scheme aroused great opposition in the medical profession, and last year the Minister of Health at Wellington set up a committee consisting of three representatives of the New Zealand Branch of the British Medical Association and three representatives of the Department of Health, with a barrister as chairman, to examine the provisions and advise what alterations were necessary to give effect to the Government's policy of making medical services available free or substantially free of cost. The report of the committee has been issued recently and is an agreed document.

The committee recommends in the first place that steps be taken to place upon the medical profession itself as a body a large degree of responsibility for the ethical behaviour of its members and for the general quality of all medical services. This responsibility is to be given to the New Zealand Branch of the Association through advisory and disciplinary committees. A disciplinary committee of members of the Association would be set up, and to it the Minister would refer for investigation and report all complaints against medical practitioners working the scheme. It is suggested that this committee might have jurisdiction to deal with complaints of professional conduct which do not come within the category of 'grave impropriety or infamous conduct in a professional respect, of which the Medical Council takes cognizance'. There would also be local investigating committees consisting of members of the Association with a medical officer of the department to make preliminary inquiries and obtain explanations from the practitioners concerned.

## Remuneration of General Practitioners

Most of the report is about methods of remuneration of general practitioners in a State service. It is agreed that a renewed attempt to introduce the capitation system could not succeed. The capitation system has advantages, but the profession in New Zealand has consistently maintained that it tends to impair the high standard of practice. When the capitation system was optional under the former arrangement, at most 51 doctors entered into an agreement of which it was a part and the number has since dwindled to 23.

A general salaried service is held to offer no solution. Nothing could be devised which would be both administratively possible and acceptable to the general body of the profession, although it is agreed that in remote areas remuneration by salary may be the only means of securing a service. The combination of basic salary with additional payments is a method on which the committee has not sufficient information and therefore makes no recommendation.

The method which it favours, except in areas which it is agreed after consultation with the Association would best be served by salaried medical officers, is a fee-for-service system. Practitioners would be required to claim on the Social Security Fund on behalf of the patient the appropriate amount payable from the fund for the service and to apply that amount in settlement of their charge. It is thought that this would best preserve the doctor-patient relationship. A scheme would be devised for the verification of services, not by the patient's own certification, the method formerly proposed, but by some check by the department, such as postal inquiry of a proportion of patients of each practitioner. In addition the practitioners will be required to maintain proper records in support of their claims, which records, with the daily diary, will be subject to inspection.

The rates of payment proposed are 7s 6d for attendance at surgery, 10s for attendance elsewhere (an advance of 2s 6d on the previous arrangement), 12s 6d for night, Sunday, or holiday attendance, and 5s for every additional quarter-hour beyond the first half-hour of attendance, but no payment is to be made when the only service is to repeat a prescription. There is general agreement that every practitioner shall have the right to charge and recover a fee additional to that payable from the fund when the circumstances require it, but patients have the right to refer any such accounts to the local investigating committee. No limit is set on the number of patients to be seen daily or the amount payable from the fund to an individual practitioner, but it is thought that an average of 30 attendances a day is the maximum.

## Specialist Services

As for specialist medical services, the same method of fee-for-service is proposed, and the criteria for the recognition of specialists are similar to those usually adopted in Britain—adequate training in the specialty, possession of higher qualification, holding of hospital or public appointment, and general recognition by colleagues. Legislation is proposed for enacting these criteria. It is thought that sums payable from the fund in respect of specialist consultations should not exceed 30s and 15s respectively for an initial and for a subsequent consultation, but many problems about specialist services are left for subsequent consideration in detail. The existing shortage of specialists can be met only by immigration as a short-term policy, and then to a very limited extent. As a long-term policy the "open hospital" system, whereby the visiting medical staff are appointed by selection from doctors practising in the district, the encouragement of the full and satisfactory use on hospital staffs of young practitioners, and the institution of additional specialist registrarships are advocated.

The development of health centres is favoured, but there must be full agreement through the British Medical Association with the medical practitioners in the areas concerned. The need for greater contact between general practitioners and the public hospitals is stressed, both by clinical courses for general practitioners of a district and by the exchange of information between hospitals and practitioners on the treatment and progress of patients.

## FACULTY OF OPHTHALMOLOGISTS INCREASED FEES

The Council of the Faculty of Ophthalmologists held a meeting on Oct 8. It was reported that as a result of representations from the Faculty the Ministry of Labour will increase the fee payable to ophthalmic medical practitioners—from 15s to £1 11s 6d—for cases referred to them by chairmen of National Service Medical Boards. The increase will be from July 5, 1948, inclusive.

The Faculty has submitted a memorandum on diplomas in ophthalmology to the examining board in England. It suggests considerable modifications of the present arrangements. Mr F A Juler and Mr Frank W Law (honorary secretary of the Faculty) have been appointed to exercise a watching brief on behalf of the Faculty on the teaching and examinations conducted under the auspices of the Orthoptic Board.

## STATUS OF MEDICAL OFFICERS OF LONDON BOROUGHS

In the administration of the personal health services under the National Health Service Act the London County Council is desirous of drawing upon the knowledge and experience of the borough medical officers of health and at the same time maintaining a link between the personal and the environmental health services, which latter remain the responsibility of the 29 borough councils (including the City Corporation). In a report presented to the Council on Oct 19 it was stated that the discussions which have taken place on this point have been influenced by the consideration that although these officers remain responsible for their present environmental health duties, it is doubtful whether such duties will suffice to enable the borough councils to obtain or even to retain officers of the same professional standing as they have recruited in the past. A scheme has therefore been worked out which will maintain the status of borough medical officers of health by making them part-time officers of the county council, subject to the general responsibility of the county councils nine divisional medical officers.

Under this scheme the borough councils will receive payment from the LCC for the part-time services of their medical officers, who will however, remain officers of their borough councils for the purpose of general conditions of service, superannuation, and compensation. If a borough medical officer does not desire to participate in the scheme or his council does not wish him to do so, the county council will itself, through its own full time staff if necessary undertake the personal health services in the borough. The medical officers who come into the scheme will work primarily in their own boroughs, but the county council will not be precluded from utilizing their services in adjacent boroughs in case of need and subject to the consent of the borough council concerned.

Up to the present 20 metropolitan borough councils have expressed their willingness to adopt the scheme without qualification, and seven have declared themselves, in varying degree, not in favour. The City of London presents a special problem, and separate discussions are in progress with the City Corporation.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non-County Borough Councils*—Dartford, Radecliffe (limited to future appointments) WallSEND

*Urban District Councils*—Denton, Droylsden, Houghton le Spring, Huyton with Roby, Redditch (restricted to new appointments), Taldesley

## National Health Service News

### Prescription of Appliances

The appliances that may be prescribed by general practitioners on Form E C 10 for National Health Service patients are listed in the NHS (General Medical and Pharmaceutical Services) Regulations, 1948 (SI No 506), Third Schedule. They are as follows.

### List of Appliances

Animal wool	Eye ointment rods
Atomizers, hand operated	Eye shades
Bandages calico, crepe, do	Finger stalls
mette, elastic adhesive, elastic	Gauzes surgical, medicated
web, flannel, indiarubber	unmedicated
many tuled, mushin, open	Gauze and cotton wool tissue
wove, plaster of Paris, suspen	medicated, unmedicated
sory, cotton triangular, zinc	Hypodermic syringes, when
paste	required for self administra
Breast relievers	tion of insulin or adrenaline
Brushes, when required for the	Hypodermic needles, when
proper administration of any	required for self administra
drug forming part of general	tion of insulin or adrenaline
medical services	Ice bags check sheeting, india
Catheters urethral gum-elastic,	rubber
soft rubber, and lubricant for	Inhalers
use with these Suprapubic	Irrigators eye (undine), nasal
rubber, and shields for use	Lints surgical, medicated
with it	unmedicated
Cellulose tissue	Pessaries ring Hodge s
Cellulose wadding	Plaster adhesive, spread or on
Chiropody felt	spool elastic adhesive
Corn and bunion plasters and	Protectives batiste gutta
rings	percha tissue, jaconet oiled
Cotton wool absorbent grey,	cambric oiled silk, including
medicated	oiled artificial silk
Douches, with rectal and vaginal	Rubber tubing
fittings	Splints including Gooch and
Dressings standard dressing	Kramer splinting and poro
BPC, wound dressing, boil	plastic but excluding walking
dressing—the last two as	calliper splints surgical boots
described in the Drug Tariff	and foot supports worn with
Droppers, when required for the	boots and shoes
proper administration of any	Sputum flasks
drug forming part of general	Syringes glass, rubber
medical services	Tampons
Elastic anklets	Test tubes
Elastic knee-caps	Tows carbolized, unmedicated
Elastic stockings	Trusses
Elastic thigh pieces	Vaccination shields and pads
Eye baths	Vaporizers

In addition, repairs and replacements of colostomy belts and cups and of suprapubic belts may be ordered on Form E C 10. Fehling's solution and Benedict's solution (qualitative) may be prescribed for diabetics to help the control of treatment.

### Certificates for Corsets

When writing a medical certificate for the supply of a corset to a patient it was formerly necessary to record on the certificate that the patient suffered from one of the disorders specified on a schedule. The schedule has now been abolished, and it is necessary only to state the diagnosis of the disorder for which the corset is being recommended.

The Chartered Society of Physiotherapy is represented on the Professional and Technical Staffs "A" Council of the Whitley Councils for the Health Service (Great Britain) which also includes representatives of the following professions: Association of Occupational Therapists, Association of Psychiatric Social Workers, Association of Remedial Gymnasts, Association of Scientific Workers, British Dietetic Association, British Orthoptic Society, College of Speech Therapists, Confederation of Health Service Employees, Hospital Physicists Association, Institute of Almoners, National Association of Local Government Officers, National Union of Public Employees, Scottish Association of Occupational Therapists, Society of Chiropractic Society of Radiographers. The Secretary of the Chartered Society, Miss M J Neilson has been appointed Joint Secretary of Functional Council 'A,' and as such is one of the representatives from the Functional Council to the General Whitley Council; the other two representatives being Mr Ben Smith (Association of Scientific Workers) and Mr F Melville (Society of Radiographers).

## HEARD AT HEADQUARTERS

### Government Hearing-Aids

The Government hearing-aids found general approval at a meeting of otologists the other day. One well-known specialist said that the criticisms of it were undeserved, and that, especially for old people and for nerve deafness, it was as good as any hearing aid that could be obtained. In America all the emphasis seems to be on smallness of size, but tiny batteries, although they are much more efficient than they used to be, do not last anything like as long. As is always the case with anything freely bestowed, some hearing-aids find themselves in the wrong ears, or, according to a Scotch otologist, no ears at all. He mentioned some recipients who, having obtained a hearing-aid from the Government, including a free battery service, found that the battery worked very well for their radio apparatus. He also mentioned the case of one man who, having already got two pairs of spectacles and a denture from the State, asked for a hearing aid to complete the outfit although he was not deaf. One of the wise things said by the otologists was that what is wanted is not so much a hearing-aid for the deafened as a speaking aid for those who talk to them.

### Don't

Perhaps the worried citizen's first reaction to Mr Gaitskell's injunctions to economize in electricity was one of aversion, distaste, despondency—one of those mild and fugitive emotions that a bouncing child feels when nanny waves a warning finger at him. Perhaps a slight dyspepsia sends him to his State doctor for a free bottle of medicine. "Do more grilling instead of frying," we are told, "Put two saucepans on one hotplate," "Bath at night and not in the morning" and so on. But we remember with a shudder the freeze up of 1947, and on second thoughts feel grateful for these warm waves of mother-love from Whitehall. We may grumble at our governesses, but we must admit that they are preferable to secret police, *Diktate* and all the other paraphernalia of the military State. Obediently, we remain the envy of the world (we like to think) for our ability to govern ourselves without undue commotion.

### Getting It Going

The new Treasurer of the Association, Mr A M A Moore, has been prevented by his acceptance of that office from continuing in the chair of the Central Consultants and Specialists Committee. He has taken a leading part in the organization of consultants and specialists in view of the new Service, first as chairman of the old Association committee, and later as chairman during the initial and not uncontroversial stages of the new Central Committee which, with its 67 or so members, crowds out the Council chamber at Headquarters. In leaving the chair Mr Moore remarked that this was the heaviest and most delicate bit of Association work he had ever undertaken. The new chairman, chosen unanimously, is Mr R L Newell, of Manchester, who did excellent work as chairman of the old Hospitals Committee, the work of which is merged into the new body.

### Not Too Exacting

Much has been said about patients who demand everything they can get under the new Service. But there is another side to the picture, represented to us in a letter from a well known practitioner in a big Yorkshire city. He says that on the whole his patients are understanding and considerate. Their attitude is very well expressed in the remark of one working woman, a typical Leeds housewife. "It doesn't seem right somehow, doctor, that we should get all this for nothing."

### PURCHASE OF SPECIALISTS' UNWANTED EQUIPMENT BY THE MINISTRY OF HEALTH

The Minister of Health has agreed to consider the purchase of any equipment no longer required by specialists—e.g., x-ray equipment. Specialists having equipment which they are prepared to sell to the Ministry should send full details of it to the Controller of Supplies (S1), Ministry of Health, Whitehall SW 1.

## CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE

### DISCUSSIONS WITH ROYAL COLLEGES

An all-day meeting of the Central Consultants and Specialists Committee was held at B M A House on Nov 4. Mr A M A. Moore was in the chair during the first part of the proceedings.

Sir Lionel Whitby gave an account of the discussions, over which he had presided, with the Royal Colleges and the Scottish Corporations concerning the representation of consultants. Certain proposals had emerged, to be placed before the constituent bodies of the conference, including the Central Committee, for a small joint committee of the bodies concerned, to speak to the Government with one voice on behalf of consultants. The terms of reference of this joint committee, its precise composition, and the procedure to be followed should one of the constituent bodies disagree with its view were included in the proposals. The composition suggested was three members from the Royal College of Physicians, three from the Royal College of Surgeons, smaller numbers from the other Royal Colleges and Corporations, bringing the total up to 11, and six from the Central Consultants and Specialists Committee.

Sir Lionel Whitby emphasized the point that this was an occasion for broad statesmanship. If such a committee were not formed the Government would be dealing with a divided profession and a wedge might be driven between the Colleges and the B M A. He reminded the committee that, after all, the majority of the Fellows of the Colleges were B M A members and he suggested that it was quite possible with dignity and without loss of real power to subscribe to these proposals.

In the course of a long debate the proposals were criticized on the ground that the new Central Committee was as perfectly representative of the consultants in every region of the country and in every branch of practice as could be fashioned, that it was democratically elected unlike the Councils of the Colleges that the method of negotiation by joint committee was an unsatisfactory one, and that the joint committee would be heavily weighted on the teaching side. Others, however, took the view that the representatives of the Colleges were likely to be in accord with the general opinion of consultants, and it was pointed out that in Scotland the feeling of separateness between the Colleges or Corporations and the general body of the profession was much less marked, if it existed at all.

Eventually an amendment against the principle of setting up a joint committee with any overriding functions was lost, and the proposal,

That it is essential in the interests of consultants that a joint committee of the bodies concerned should be established to speak for consultants with one voice

was carried by 42 to 2.

The following terms of reference were agreed to *nem con*.

To represent the views of consultants to the Government on all questions of general policy, and to keep itself informed on all matters affecting consultants, the definition of the field of general policy and any delegation or division of labour to be determined by the Committee in agreement with the constituent bodies.

A further proposal was approved that where a constituent body differed from the joint committee it should be entitled to have its view represented to the Government, provided that, before such representation was made, a conference between representatives of the joint committee and of the constituent body should be held in an endeavour to reach agreement. It was also agreed that joint secretaries should be appointed, one by the Colleges and Corporations together, and the other by the Central Consultants and Specialists Committee. On the question of composition there was some debate, but the original proposal, which provided for the representation set out below, was carried by 39 votes to 9.

Royal College of Physicians, 3, Royal College of Surgeons, 3, Royal College of Obstetricians and Gynaecologists, 2, Royal College of Physicians Edinburgh, 1, Royal College of Surgeons, Edinburgh 1, Royal Faculty of Physicians and Surgeons, Glasgow, 1, British Medical Association, 6.

### Election of Chairman of Committee

This controversial business having been disposed of, the committee proceeded to elect a chairman, Mr Moore having taken

Chair only during the initial stages having been elected. The Secretary of the Association felt himself unable to continue in the other capacity. On the proposition of Mr. Simson Hall, seconded by Dr. R. G. Gordon, Mr. R. L. Newell was unanimously elected. On taking the chair he expressed the thanks of the committee to Mr. Moore for his initiative in forming the committee and guiding its early stages.

### Specialist Spens Report

The committee then turned to the completion of the business which had been left over from the last meeting. The first matter concerned points raised by regional committees in relation to the report of the Spens Committee. The Secretary (Dr. Charles Hill) made a statement on the general question of Whitley machinery, now under consideration with the Ministry. In general, the National Council for the medical profession would work through three committees—for specialists, general practitioners, and public health officers—the recommendations of each committee being subject to approval by the Council with the employing bodies on the one side and the representatives of the profession on the other. The general practitioners had got the Minister to concur in the view that, as soon as the Whitley machinery was established, general practitioners would be free to raise within that machinery the question of the betterment factor, which, if the two sides did not agree, could be referred to arbitration. He suggested that on this point specialists should follow the same course as general practitioners, and that this should be one of the first issues raised within the Whitley machinery negotiations.

The committee endorsed a resolution from the N.W. Metropolitan Regional Committee as to the basis on which the computation of the betterment factor should be made.

Two other matters arising out of the Spens Report were the subject of resolutions. One was that in all cases where a specialist transferred from one hospital appointment to another his remuneration should be fixed in relation to his seniority in the Service. The other was that fees received for medico-legal work, special reports, lectures to and examination of nurses, and the like, which had been regarded in the past as undertaken by the specialist in his personal capacity, should be retained by him, whether he was in full-time or part-time contract with a regional hospital board.

### Interim Terms

Several questions relating to domiciliary visits had come forward in the regions and were referred to the committee. The committee passed a resolution that there should be payment for all domiciliary visits undertaken. This arose out of the general question of limitation upon payment for domiciliary visits. Instructions have been issued by the Ministry of Health to regional boards to use their discretion in applying the overriding payment, but it was not thought that this was a satisfactory arrangement.

The committee felt also that additional fees should be payable where specialists found it necessary to take special equipment to the home of the patient, and that radiologists and anaesthetists providing their own apparatus and materials for domiciliary visits should be suitably reimbursed.

The question of nursing-homes in connexion with domiciliary visits gave rise to some discussion. It was stated that in a maternity case at a nursing-home, if the attendance of a paediatrician was necessary this could not be given within the Service because the mother, although a public patient, was in a nursing home and not at her own home, in other words, the arrangement for the payment of fees for domiciliary work did not extend to nursing homes. It was agreed to refer this matter to the regional committees for their opinion.

Further resolutions were that specialists should be paid for every session required of them by regional boards or boards of governors irrespective of the number of sessions in any one week, also that specialists rendering part-time services should be paid an annual salary assessed on the number of half-day sessions required with due regard to liability for emergency visits, annual leave, deputy arrangements with colleagues and so forth, and that the assessment should be made in consultation with the specialist concerned.

The attention of the committee was drawn to the fact that in certain regions the proportion of pay-beds to public beds

was being disturbed, in spite of the offered assurance that during the interim period pay-bed accommodation would remain as at the appointed day. The Ministry had been already reminded of its assurance and had been asked that a direction should be given to regional boards that no rearrangement of pay-bed accommodation should be made before March 1949. It was also decided to ask regional committees for any evidence of change of use of beds—that is to say, change of what had been beds with professional fees charged to patients to another use, amenity or public.

The feeling was expressed that a move should be made to secure the deletion of the Second and Third Schedules to the Regulations dealing with pay-bed accommodation in hospitals. These schedules set out the maximum charges for specialist professional services, and it was pointed out that the schedules were prepared for provident associations having in mind only persons with limited income so that to introduce them on a wider basis was extremely unfair. The possibility of changes in the Amending Act which would render the schedules unnecessary was considered. It was agreed to ask the executive committee to look into this matter before coming to a decision.

An executive committee was set up in the course of the meeting in view of the great amount of work which was before the parent committee. It will meet between the meetings of the main committee, prepare and refine the agenda, and take any action which is urgently necessary, reporting, of course, to its parent. Much other business was before the committee, including a report on discussions between representatives of the Ministry and those members of the Negotiating Committee who are engaged in consultant and specialist practice. This report dealt with cases of hardship caused by the interim terms, the financial position of junior hospital staff, allocation of pay-beds, and various other matters.

## Questions Answered

We publish here the answers to a selection of questions that seem to be of general interest.

### Superannuation Scheme and Locums

**Q**—Is the superannuation scheme applicable to a practitioner doing postgraduate study and undertaking week-end locums and occasional evening surgery work for various doctors?

**A**—The regulations do not refer specifically to a practitioner acting as a locum. An assistant, however, is defined as the employee of a practitioner on the list of an executive council, such employee being wholly or mainly engaged in assisting his employer in the actual discharge of his duties in that capacity (i.e., in the provision of general medical services). On this analogy a locum in casual employment would not be superannuable under the regulations by virtue of that employment. A locum who is wholly or mainly engaged in assisting practitioners on the lists of executive councils, however, would be well advised to apply to the Health Services Superannuation Division of the Ministry of Health, 28, Princes Gate, London S.W.7 for special arrangements to be made for his inclusion in the superannuation scheme. A practitioner who is a member of the superannuation scheme by virtue of other employment (e.g., hospital appointments), and who combines with post-graduate study occasional work as a locum may preserve his superannuation rights by applying to the Minister under the leave of absence provision.

### Superannuation for House-men

**Q**—Are practitioners who are doing junior hospital appointments for periods of six months or a year liable to contribute to the superannuation scheme?

**A**—Yes, and their hospital service will count towards pension and other benefits.

### Superannuation for Elderly Practitioners

**Q**—In what circumstances can a doctor over 65 years of age participate in the superannuation scheme?

**A**—A doctor who is over 65 years of age on entering the National Health Service cannot participate in the superannuation

scheme and is therefore not liable to have superannuation contributions deducted from his remuneration. A doctor who is on an executive council list may apply at any time between the ages of 60 and 65 for an extension of pensionable age up to but not beyond the age of 70. If his application is granted he will continue to pay superannuation contributions during the extended period and his extended service will be reckonable in assessing superannuation benefits. For example, the minimum qualifying period for pension is 10 years' service. The extension allows a practitioner of 59 years of age on entry to put in the 10 years' service required to qualify for a pension on retirement at or after age 69. The practitioner is not bound to retire from practice when any benefits to which he may be entitled under the scheme become due, but after pensionable age is attained superannuation contributions will cease and service will cease to be reckonable for the purpose of benefits. In considering an application for extension the Minister will consult the executive council for the area concerned and will ask that body to seek the views of the local medical committee.

#### Partnerships and Superannuation Payments

**Q**—My partner and I have both entered the Service. We each have approximately 3 000 patients on our lists. Is superannuation payable on the basis of the remuneration received from the executive council or on the basis of the partnership shares?

**A**—It is open to doctors practising in partnership to have superannuation deductions made in proportion to their shares in the practice instead of on the remuneration actually paid to them by the executive council, provided particulars of the partnership agreement are disclosed to the executive council.

#### Benefits for 30 Years' Service

**Q**—I entered the Service on the appointed day as a general practitioner aged 35. My wife is the same age. I expect to complete 30 years' service and to retire at 65. Assuming my net remuneration to be £1 200 a year, what benefits shall I receive under the superannuation scheme?

**A**—Assuming this practitioner did not exercise his option to pay a reduced superannuation contribution and to receive a modified pension on account of the National Insurance Retirement Pension he will receive on retirement at 65 a pension of £540 a year (i.e.,  $1\frac{1}{2}\%$  of his total net remuneration of £36,000) and a lump sum retiring allowance of £540 (i.e.,  $1\frac{1}{2}\%$  of £36,000). Should he die at 67 after drawing his pension for two years, his widow would receive a widow's pension of £180 a year (i.e.,  $1\frac{1}{3}$  of his own pension of £540 a year). It should be noted that the option to pay a reduced superannuation contribution and to receive a modified pension is open only to those practitioners who were in the Service on July 5. For those who entered after July 5 the reduced contributions and modified pensions are compulsory. The modification is made on account of the fact that the practitioner will be paying 6s 2d a week under the National Insurance Act and will qualify for a pension under that Act of 26s a week on retirement with an additional 16s a week in respect of his wife.

#### Superannuation Contributions of Assistant

**Q**—Can you tell me how as an assistant I go about making my contribution to the superannuation scheme in the National Health Service? Are the contributions made through my principal or are they made direct by myself to the NHS authorities?

**A**—For the purpose of the superannuation regulations the principal is the employing authority in relation to his assistant. The principal is entitled to deduct from the assistant's salary 6% in respect of superannuation contributions. The principal is required to pay as an employing authority a contribution of 8% of the assistant's salary. The assistant's 6% and the principal's 8% must be remitted by the principal to the local executive council. Similarly as an employer, the principal is required to place a 9s 1d stamp on the assistant's national insurance card each week and may deduct the assistant's contribution of 4s 11d weekly from his salary.

### A Canadian View of the NHS

**SIR**,—For three months I held a house appointment in a comparatively small hospital in this country under the NHS, I have therefore been deeply interested in the developments in medical practice which have occurred in recent months. May I draw a comparison between these developments and the conditions which exist in British Columbia and certain other Canadian Provinces? And may I also offer some criticism of the British medical profession which I hope will not be completely lacking in constructive elements? Needless to add that I write with considerable humility, as befits a recent arrival to Britain.

In British Columbia the Blue Cross Hospital Association together with Medical Services Associated provide that all hospital, investigative, and medical fees of whatever sort are paid on behalf of members and their families. (There is a limit of thirty days hospitalization per year for each insured person.) Membership of these organizations is available to large sections of the population who are regularly employed, membership in them is voluntary, and contributions to support them are about equally divided between the member and his employer. Having joined these organizations, the member and his family are assured of adequate medical care in almost any circumstances.

From the political point of view, the important feature of the MSA is that it is administered by a group which includes only members of the profession. The fact that the MSA itself is directly under the control of the profession has put it in a very strong position—strong both from the point of view of remedying the grievances of individual practitioners, or explaining them when they cannot be remedied, and strong also in dealing with the general public in the matter of publicity and with the various local, provincial, and federal Government agencies. The MSA, together with the provincial medical organization (which is, of course, a branch of the Canadian Medical Association) represents the profession in a very adequate and effective way.

The NHS is in operation, and only the most robust conservative would say that it is not here to stay. But at what cost?

Before the appointed day the Ministry of Health in England had made administrative preparations which, in the event, have proved and are still proving inadequate. Bureaucratic measures have invaded medical practice from every side, and the general practitioner has found himself, *volens nolens*, an administrator and an arbiter of questions which he has no desire to arbitrate, such as the rights of certain individuals to extra petrol. Benefits have been promised which there is no likelihood of fulfilling, non-existent health centres have been used to promote what the Americans would call the "sales appeal" of the Service, some benefits which to the uninitiated Canadian appear frankly ridiculous are freely available. Let me instance spectacles to short-term visitors from other countries and expensive medicines often prescribed for inadequate reasons.

Far from the NHS "pooling the hospital resources of a region for the good of all," its practical result in the area where I worked could rather be described as setting one hospital against another in a bitter rivalry to preserve that most valuable asset—an empty surgical bed to be used for emergencies only.

What is far more serious than these obvious shortcomings, which were expected at least to a certain degree is the passing not only of the administrative responsibility of medical practice but its medical control from the hands of the medical profession acting under the law to those of the Minister of Health—acting under the law, it is true, but guided by directives for which he alone is responsible. And in these directives the Ministry of Health does not appear always to have had the benefit of the best medical advice. How else explain the fact that a general practitioner who has treated a given patient for perhaps 20 years is unable to prescribe a surgical appliance which a house surgeon, qualified six months, can prescribe in 20 seconds? One cannot feel that any man who has spent his active adult life in the arena of party politics, which is the needful prerequisite for attaining Cabinet rank, can at the same time have had the benefit of the years of medical training and experience required to grasp the needs of complex medical problems.

I suggest that unless a central body which truly has the mandate of the profession and its undivided support is willing to fight to regain at least a measure of the administrative control of the scheme as a whole the present unsatisfactory situation will persist. The Negotiating Committee was faced with an almost impossible task—that of representing the interests of a group who in fact had never forcibly and solidly expressed their true desires. One can have nothing but admiration for the democratic methods which were used, but the practical consequences are now here for all to see. The profession as a whole, faced with the almost irresistible pressure of the State has been forced to give way in every vital point at issue.

I should add that I am not a diehard Conservative and by no means opposed to the professed objectives of the NHS. The contrary is the case in my view no reasonable person would oppose any measures which promise to improve the general health. But, unless a reservoir of good will exists which will lead to co-operation between the administrators of the scheme and those who actually do the work for which the scheme was set up there would appear to be little chance of its success. The proper basis for such co-operation would appear to me to be the placing of administrative responsibility and high-level medical decisions where they properly belong—in the hands of those best qualified to make such decisions—I am etc.

London WC1

DOUGLAS FINDLAY

### Relation with Executive Councils

SIR—Dr Robert Forbes (*Supplement* Oct 23, p 147) oversimplifies the important issues raised by Drs Hugh M. Tucker and D. Gwyn Jones (*Supplement*, Oct 9, p 134). It may have been true to say that, before the passing of the National Insurance Act 1946 we were not in fact workmen but independent contractors. I doubt if that is true to day. In order to appreciate the position with some degree of clarity it becomes necessary to define certain terms which are employed in both the National Health Service Act and the National Insurance Act. These terms are, (1) workman or servant, (2) employed and employment, (3) contract of service.

(1) A servant or workman is an agent who works under the direct or indirect supervision and under the direction of his employer. He is engaged to obey his employer's orders from time to time. The test which distinguishes the servant from other agents or independent contractors is the fact that the servant is much more under the control of the employer than the latter.

With an independent contractor the employer stipulates for certain results—e.g. to build a house, to write a book, to perform at a concert etc., and leaves the employee, within limits, to produce the result as seems best to the employee. The independent contractor in other words, is bound by the contract and not by the orders. In the case of a servant the master retains the right to choose the means and methods as well as the result. This is what the Minister of Health retains by virtue of his powers in the National Health Service Act and Part 1 of the First Schedule of Statutory Instrument, 1948 No 506. I would therefore submit that a medical practitioner employed by the Minister of Health through his agent the local executive council, is now a workman or servant within the meaning of the law of master and servant. The same submission will apply in certain cases to a consultant or specialist who is employed by his direct principal, the regional hospital body.

I do not subscribe to the opinion that our contract is one for services rather than one of service. Although we are now designated in the National Insurance Act as "self-employed" the Minister of Health or the regional body as employer controls us as servants, to a greater or less degree, in the manner in which we do our work. By virtue of the Minister's wide and extensive powers the conditions of employment may be subtly and insidiously altered by Statutory Instruments so that the Minister or regional body may in the future command in full the manner in which we do our work. In the nineteenth century the doctrine of the "implied command of the master prevailed. To-day a servant comes within the theory of 'scope of employment'.

(2) Employed and employment are defined in the National Insurance Act in Section 1(2) and in Section 78 and include trade business profession office or vocation. A person who is gainfully occupied for the purposes of national insurance is one who is engaged in any trade business, profession office or vocation and is wholly or substantially dependent thereon for a livelihood. (The italics are mine).

Self-employed persons include small traders and all professional persons unless, though qualified they are paid a salary or other remuneration under a contract of service. Therefore although the Minister of National Insurance designates us "self-employed," we are in fact by the wording of the National Insurance Act servants by virtue of our salaries remuneration and emoluments, on which we are wholly or substantially now dependent for a livelihood.

(3) The distinction between a contract of service and a contract for service or services was given by Lord Justice Fletcher Moulton in *Simmons v Heath Laundry Co* (1910) 1 KB at p 550. The greater the amount of direct control exercised over the person rendering the services by the person contracting for them the stronger the grounds for holding it to be a contract of service, and similarly the greater the degree of independence of such control the greater the probability that the services rendered are of the nature of professional services and that the contract is not one of service.

It would be interesting to hear Dr Forbes's views on the nature of the employment and the type of contract under which assistants will be engaged for training. Will it be a "contract of apprenticeship" which is not defined in the National Insurance Act?—I am etc.

J ARTHUR GORSKY

### Medico-legal Responsibilities

SIR—I hope you will grant me some of your valuable space to reinforce and supplement the views and advice conveyed in Dr Robert Forbes's letter under the heading "Relations with Executive Councils" (*Supplement* Oct 23, p 147). Everything said in that letter concerning the importance of membership of a recognized protection society for general practitioners in contractual relationship with local executive councils applies with equal, if not greater, force to those who are in salaried appointments. This Society has ample experience of the pitfalls into which, for example Service and municipal medical officers may fall, and the last three months have produced a spate of inquiries from our members concerning the interpretation of regulations issued under the National Health Service Act and their application to individual circumstances. Indeed, many of the recent statutes enacted so speedily and giving wide enabling powers to the Minister concerned have a particular application to the medical profession.

The recognized protection societies will have an ever increasing role to play in providing expert advice on personal problems and protection against bureaucratic injustice as well as defence and indemnity against actions for damages in tort or contract, and advice and defence in criminal prosecutions which have a professional association.—I am, etc.

ALISTAIR FRENCH  
Secretary

Medical Protection Society

### Smaller Maximum Lists

SIR,—Since July 5 there has been considerable dissatisfaction among general practitioners owing to excess of work and the necessity of having a large number of patients on one's list in order to obtain a reasonable income. I think it was a great mistake in the Act to allow a doctor to have up to 4,000 patients on his list and I agree with Dr S. T. Pybus (*Supplement* Oct 16, p 143) that no practitioner can do justice to his patients if he has anything like this number to deal with. However those of us who are compelled to keep big lists for economic purposes know that this creates many of the conditions that the profession, our wives and our patients complain of.

I hope therefore that every step will be taken by the appropriate authorities to limit the maximum number of patients allowed to a general practitioner to 2,000, or at the most 2,500 and to raise the capitation fee to 40s for the

first thousand, a lower rate for the second thousand (and a still lower rate for the remaining five hundred, if 2 500 were allowed) This would then allow each practitioner to give his patients the full time they need if we are to practise real medicine and at the same time would ease the conditions of sweated labour from which doctors and their wives now suffer —I am, etc,

Slough Berks

H TUDOR EDMUNDS

### NHS Remuneration

SIR,—The circular letter from Dr Charles Hill (*Supplement*, Oct 23, p 145) concerned mainly with general practitioner remuneration makes most depressing reading Having searched carefully through and sifted all the chaff I found the two grains of wheat—to wit, seventeen shillings and five pennies No doubt there will be additional payment for maternity work and immunization, but why not throw this in with the two grains of wheat? It matters little now—

What I should like to know is what was discussed during the nine months' meeting with the Minister and his henchmen Was the undignified subject of remuneration discussed? If so was it "the silver in his tongue or the fire in his belly" that frightened them? I would just like to make two forecasts (1) Any attempts by the profession to have the capitation fee raised will meet with long and stubborn opposition (2) At the first opportunity steps will be taken to reduce capitation —I am etc

Exeter

G F MAGURRAN

### Rural Practitioners

SIR—At a recent Divisional meeting the plight of the rural practitioner under the NHS Act was ventilated in the light of three months' experience It was pointed out that several practitioners were in serious financial difficulties owing to the immediate curtailment of income resulting from the system adopted of "payment on account" The absence of an advance payment for drugs and mileage has resulted in some cases in the doctor being obliged to maintain his current expenses by increasing his overdraft, pending payment by the executive councils, which under the present arrangement may not be completed for twelve to eighteen months

Furthermore it was considered that the proposed scale of drug and mileage allowance is totally inadequate to permit the rural doctor to meet his domestic and practice commitments The financial pressure likely to be brought to bear upon some of us in the next few months in the shape of bank charges may well prove overwhelming and one which we should not be expected to bear

To double the Mileage Fund (£600 000 to £1,300 000) when many rural practices show an increase of three times their registered patients as compared with the NHI is in effect paying less per head, at a time when running costs, repairs, and purchase prices of cars are more than double their 1939 value and illustrates how unrealistic some of our administrators are

As this letter is based upon facts, the following examples which are by no means isolated cases, are quoted

(1) Drs A and B (partners) Area of practice, 200 sq miles, NHS patients (including 800 NHI) 2 400, private patients, 200, mileage 50 000 p.a. no dispensing no hospital, NHS cheque first quarter £461 practice expenses (accountants' figures excluding mileage policies and purchase of cars), £350 per quarter, surplus, £111

This means each partner receives £55 10s for three months' work —i.e., £4 12s per week out of which he is expected to keep his domestic household, pay life insurance and income tax save a little —i.e., the purchase of a new car and, last but not least, pay 6s 2d per week national insurance

Even the £300 quarterly mileage allowance which the executive council say will probably be paid is "chicken feed" when one considers Dr A is a married man with four young children (two at boarding school and in the not very distant future four will be at the same time), Dr B has an outstanding loan account of £800 together with an overdraft of approximately £800

(2) Dr C (single practice) Area 150 sq miles, NHS patients 1 500, private patients, nil mileage 25 000 p.a. dispensing, no hospital, NHS cheque first quarter, £283 expenses per quarter

Dr C has loans, overdrafts and mortgages of £7 000 He is therefore unable to repay of £110 per quarter He is therefore

left with £48 (£4 per week) to maintain his practice and live He has three children, two of whom are at boarding school He is overdrawn at the bank to the limit of his security and his bank charges are mounting daily He cannot meet his chemist's bills His position is serious

There would appear to be only two satisfactory methods of bringing the rural practitioners into line with their urban brethren (1) Adequate mileage allowance, paid quarterly (2) If this is insufficient, inducement payments, as recommended by Drs McConaghy and Edgcombe Rowe (*Supplement* Sept 18, p 125)

It does not seem to be sufficiently appreciated either by those who direct our policy or by the various medical committees throughout the country, who are generally composed of a disproportionately large number of urban and industrial practitioners that the rural doctor is an essential link in any medical service and that he has an exceptionally onerous and responsible job If some definite steps are not immediately taken to improve his lot it will lead to his inevitable departure to the urban areas where he would be better off as an assistant, with a resultant lack of medical services to a community who in these days are the essential contributors to the nation's larder—I am, etc,

L R ROUTLEDGE,  
Honorary Secretary Hexham Division

### Remuneration of GPs

SIR,—I am enclosing a cutting from a prominent Northern daily newspaper which publishes part of a letter sent by Mr Bevan's Private Secretary to a local general practitioner In this letter the secretary states "Mr Bevan asks me to remind you that the remuneration of general medical practitioners in the National Health Service was agreed with the representatives of the medical profession, who stated during the course of the negotiations in connexion with the new Service that they did not quarrel with the financial proposals The remuneration is, in fact based on the recommendations of the Spens Committee on the Remuneration of General Practitioners and Mr Bevan is satisfied that it does implement those recommendations"

In view of the wide publicity given to this statement I think that the profession is entitled to know how the matter stands Either we have been kept in the dark by our representatives who have agreed to financial conditions without consulting the profession or the statement by the Minister is untrue If the latter is the case it is surely high time that the Negotiating Body made it perfectly clear to the Minister and to the public that the doctors are far from satisfied with the financial provisions of the Act Letters coming from all parts of the country show that the general medical practitioners are facing a financial crisis of the first magnitude This crisis can only be averted by strong action at once before it becomes a calamity—I am, etc,

Leeds

M HUTCHINSON

### Employment of Assistants

SIR,—Why does the *Supplement* of Oct 30 omit to point out that the terms now promulgated by the Minister for the employment of assistants differ not at all in their main features from Paragraph 6 of the circular "Remuneration of General Practitioners" sent to us in April? All that is new is a list of conditions under which grants will be paid

Was I the only nitwit in this country who thought in April, May, and June that if one had to apply for and obtained permission to continue to employ an existing assistant the terms of Paragraph 6 would automatically apply, at least until such times as the Ministry was able or willing to define more precisely what was really intended? Nothing in the paragraph implied that it was to apply only at some undetermined future date or that no existing assistants could be carried forward into the Service, nor in my own case, was there any reason to suppose that anyone in Whitehall knew whether my assistant had been with me three weeks, three months, or three years My cheques for the first quarter, admittedly "on account" amounted to £442 The services of my assistant and his car expenses cost me some £280

Dr M K Dorothy Douglas (p 154) writes "Thus the inducements to enter the scheme are being withdrawn now

that we are safely in. How right she is. The trap was most cunningly baited in half a dozen different ways. Some of us were attracted by one illusory lure others by another. More of us probably were moved by fear—fear for our children, our wives and for ourselves. How many of us already wish that we might awake and find that it had all been a nightmare!—I am etc

Launceston Cornwall

DONALD M. O'CONNOR

Paragraph 6 of the circular on remuneration is as follows: "6 Grants for the supervision of the training of assistants will amount to £150 a year, plus the salary of the assistant and boarding expenses (together not exceeding £700 a year) with an allowance not exceeding £150 a year if an additional car is necessary. Further details will be announced later.—ED, B.M.J."

## POINTS FROM LETTERS

### Capitation Fee

Dr M. BRADFORD (Atherstone, Warwickshire) writes: "I fully agree with Dr S. T. Pybus (*Supplement*, Oct. 16, p. 143) that the proposed capitation fee is not enough and that the rate per patient should be £2. I strongly disagree that the capitation fee should be less than £2 per head after the first thousand. My list of patients on the National Health Service is considerably in excess of 2,500. General practitioners like myself who have large lists of patients have been attacked both by their own colleagues within the medical profession and by laymen, notably the Minister of Health, Mr. Aneurin Bevan. In this letter I wish to vindicate the man or woman who has a large practice. I believe that a large practice can be made and maintained only by hard work, careful consideration of each patient, continued study of each case, and a willingness to obtain as much information as possible every time from friends and family and by consultation with colleagues in every branch of medicine. I agree with Dr. Pybus's statement that 2,500 patients are sufficient for any doctor. When a doctor has more than that number he must overwork. What is the remedy? Dr. Pybus says that the successful practitioner should be penalized for being successful. The logical sequel is that the brilliant consultant would be paid less for every consultation over a certain number and the excellent surgeon less and less for each operation as he gets better and better at his work. I hope that our profession will refuse to permit reduced capitation fees in any circumstances. The only remedy for overcrowded practices is a better capitation fee, and £2 per patient for 12 months' attention is a reasonable amount. The improved capitation fee would attract more doctors and the best brains into general practice. On the other hand the present capitation fee of 18s per head will cause annoyance and a miserable existence for a larger number of general practitioners. It will also accelerate the present tendency for medical students to become specialists. The present attitude of making the general practitioner do more and more for less and less will result in fewer and fewer going in for general practice. The Health Minister, after promising all sorts of things to the people, now warns them not to abuse their opportunities. He also warns the general practitioner of his great responsibility and informs him that over-prescribing is as bad as under-prescribing. British general practitioners do not need to be warned of their responsibilities. They have kept up a high standard of work in the past and they will maintain that standard in the future if it is at all possible. I believe it will not be possible unless we are paid much more than at present."

### Victims of Health Act

"M.D." writes: "The general practitioner is not the only victim of the Health Act. Two of the senior surgeons at my hospital said last week, (a) 'I have not had a private patient for 12 days,' (b) 'I have earned seven guineas in the last fortnight, and most of my colleagues tell the same tale. The expenses of my own practice used to absorb a third of the fees, now, at £1,200 a year, they considerably exceed the takings. Neither practice nor family expenditure can be altered at a moment's notice. As Lord Catto said recently with taxation at its present level not even a Scotsman can save. Upon what is it supposed that the consultant is to live until next March?'"

### Employees' Certificates

Dr W. M. WATSON NEWTON (Birmingham) writes: "I find in my practice that I am as busy this autumn (usually my slackest time) as I generally am in the spring and I do not altogether blame the patients, many of whom are compelled to waste their time in my waiting room and my time in the surgery because they must have a certificate for some firm or municipal department to prove that they are unfit to work even for a day or have had time off to seek doctor's advice and a second one in many cases to state that they are now fit to resume work. I have had an unfortunate patient travel from Birmingham to Coventry only to be sent back for a

private certificate of fitness before being allowed to start. I wish something could be done to free the working population from this tyranny and incidentally relieve us of many unnecessary consultations."

### Payment of Locumtenent

Dr R. NUTT (Godalming, Surrey) writes: "Could not a simple scheme be evolved by which a locumtenent should derive his salary from the State rather than from the unfortunate general practitioner when he is incapacitated through illness, or when he takes his annual holiday for a period of, say, three to four weeks? I would also like to entirely support Dr S. T. Pybus's letter (*Supplement* Oct. 16 p. 143)."

## Association Notices

### B.M.A. LIBRARY

The Council has decided that owing to fuel and lighting restrictions the Library hours must coincide with the General Office hours. From Nov. 15 until further notice the Library will be open from 9 a.m. to 5 p.m. on Mondays to Fridays and 9 a.m. to 12.30 p.m. on Saturdays.

### KATHERINE BISHOP HARMAN PRIZE

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1949. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949 but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine.

The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1948.

### VACANCY IN CENTRAL COUNCIL—GROUP XII (NORTHERN IRELAND) 1948-9

As Dr J. H. P. Giff was the only nomination by Representatives of Constituencies in Group XII to fill the vacancy caused by the resignation of Dr J. M. Hunter, Dr Giff is accordingly elected a member of Council for the year 1948-9.

CHARLES HILL,  
Secretary

### Branch and Division Meetings to be Held

**GREENWICH AND DEPTFORD DIVISION**—At Miller Hospital, Greenwich High Road, S.E., Wednesday, Nov. 17, 8.30 p.m. B.M.A. Lecture by Mr R. C. Brock: "The Present Position of Thoracic Surgery." All medical practitioners in the area of the Division are invited.

**HENDON DIVISION**—At Hendon Hall Hotel, Monday, Nov. 15, 8.45 p.m. Dr Denis Hutchinson: "Working of the National Health Service in Particular Relation to the Functions of the L.M.C."

**NORTH OF ENGLAND BRANCH**—At Royal Victoria Infirmary (New Lecture Theatre), Newcastle upon Tyne, Thursday, Nov. 18, 7.15 p.m., clinical demonstration by Professor F. H. Bentley: "Gastrectomy for Duodenal Ulcer." 8.45 p.m. address by Professor A. Kennedy: "The Use of the Mental Health Services."

**ST. PANCRAS DIVISION**—At B.M.A. House, Tavistock Square, London, W.C., Friday, Nov. 19, 8.30 p.m. Opening meeting of the session 1948-9. Mr J. C. Gilbert O.B.E. and Dr Frank Gray will answer questions on the working of the new Health Service.

**WESTMINSTER AND HOLBORN DIVISION**—Joint meeting with Charing Cross and Fulham and Kensington and Hammersmith Divisions at Postgraduate Medical School of the Royal Cancer Hospital, 24, Old Gloucester Gardens, Fulham, S.W., Wednesday, Nov. 17, 8.30 p.m. Dr C. C. Worster Drought: "Intra-cranial Tumours." Open to all medical practitioners in the area of the Divisions.

# BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 20 1948

## THE PHYSIOLOGICAL BASIS OF NEUROMUSCULAR DISORDERS

BY

Sir HENRY DALE, OM, GBE, FRCP, FRS

To-day's discussion is to deal with the bearing of recent physiological observations, and of the interpretations which have been applied to them, on clinical studies of neuromuscular disorders. The choice of myself as opener, and of subjects by those who are to follow me as invited contributors, would appear to direct our discussion chiefly to the clinical applications of the large and growing body of evidence for the transmission of effects from the endings of nerve fibres to contiguous responsive cells by the liberation of chemical transmitters.

### Chemical Transmission at the Periphery

We may take for granted, as generally accepted, that the effects of impulses in the efferent post-ganglionic fibres of the autonomic nervous system are so transmitted to involuntary muscle and gland cells by the liberation of one of two known transmitters—adrenaline (sympathin) and acetylcholine. In this case the nature of the transmitter determines also whether the effect produced by the arrival of nerve impulses at the endings will be augmentation or inhibition of a spontaneous activity, and the two transmitters commonly produce opposite effects on the same layer of involuntary muscle. How they do so is one of the fundamental problems of pharmacology, but we might note in passing that it does not seem to have any intelligible relation to the hypothesis, which we shall meet later, according to which conduction of excitation along nerve fibres and from their endings to receptive cells, is one uniform and electrically conducted process, everywhere due to the depolarizing effect of liberated acetylcholine.

For the purpose of the discussion I think that it must be said that these phenomena of chemical transmission from peripheral involuntary nerve endings, though we have been considering them as theoretical possibilities for nearly 45 years and have known them as well-established experimental facts for more than 25 years, have had relatively little influence on the understanding of clinical conditions. Their main effect on clinical practice has been, I think, to clarify understanding of the actions of well-known medicinal agents such as atropine, physostigmine, adrenaline itself, and the ergot alkaloids, and to guide the search for new ones such as carbachol, prostigmin, the fluorophosphonates and simpler organic phosphates, ephedrine, and others. It may be, however, that the application of this more intimate knowledge concerning the mechanism of the

control of such involuntary functions has not yet been exploited to its full value in clinical medicine.

I suspect that it may have been largely forgotten by now that Otto Loewi, many years before his epoch-making experiments on chemical transmission, had described in Graves's disease a supersensitiveness of involuntary muscle to adrenaline of such a kind that the mere instillation of it into the conjunctival sac of the patient produced abnormally a dilatation of the pupil. I wonder whether there may not be other abnormal reactions of involuntary muscle to the transmitters or their analogues yet to be discovered which might be useful in diagnosis or indicative of aetiology. I know, of course, that there has been a voluminous literature on what were called the "vagotonic" and the "sympathicotonic" diatheses, and I am not unaware of the perils to which a sprightly imagination may expose its owner when given the freedom of such clinical borderlands. I only raise the question, then, whether the positive knowledge and the specific reagents which we now possess might not be used to commit some of such conceptions to the crucible of experiment, and to enable us perhaps, with the refined product, to approach nearer to the ideal of that stimulating sceptic among my clinical teachers the late Mr Barrett Lockwood, who used to offer to believe in a diathesis when one of his physician colleagues could show it to him "on a plate."

Before leaving the transmission of nervous effects at the periphery to involuntary effectors we ought to take note of the suggestion that histamine may act as a third transmitter. The evidence, not yet by any means so definite as for the two already mentioned, indicates that histamine may be released by the so-called "antidromic" nerve impulses at the endings of those terminal nerve branches which supply the networks of minute blood vessels to the skin.

### Transmission at Ganglionic and Nerve-to-end-plate Synapses

I have no doubt that to-day's discussion will centre mainly on the interpretation of various defects of nervous and muscular function in the light of the evidence obtained in more recent years for a chemical transmission of the excitatory process from the endings of motor-nerve fibres to the motor end-plates of voluntary muscles, from the endings of preganglionic nerve fibres to the nerve-cells of autonomic ganglia, and perhaps at certain comparable synaptic junctions in the central nervous system. In all the cases concerning which we have clear evidence so far the

transmitter is acetylcholine, and the actions of that substance on the motor end-plates and on the autonomic ganglion cells are those which are grouped together as its nicotine actions, because these structures are sensitive to acetylcholine after atropine has annulled its peripheral effects on the involuntary effectors and are, on the other hand, made insensitive to acetylcholine by excess of nicotine, by curarine, or, as we must bear in mind, by a persistent excess of acetylcholine itself.

Before we consider particular clinical abnormalities in relation to this conception we ought to have a clear idea of what it involves, and to note that it cannot yet be regarded as accepted by all who concern themselves with such matters. In the form in which my colleagues and I have advocated it the theory postulates chemical transmission at motor myoneural and ganglionic synapses as a process essentially different from that by which the excitatory process is conducted along either a nerve or a muscle fibre in continuity. It is incompatible, accordingly, with the facts that the excitatory transmission is irreciprocal only at these junctions and that it is blocked only at these by poisons such as curare or modified by such as physostigmine, contrasting sharply in these respects with conduction along continuous fibres, which goes equally well in both directions and is not elicited, stopped, or in any way modified by acetylcholine itself or by the alkaloids mentioned in concentrations even much greater than those which are so effective at the synapses. It may be said, further, that our conception restricts the transmitter function of acetylcholine to the sites where nervous impulses demonstrably liberate it, where it can be shown to act in the manner required, and where its action is annulled or modified by agents which comparably alter the effects of nerve impulses incident there.

We are content, while others seek further evidence, to accept the prevailing view of the momentary process of excitation at a point on a nerve or muscle fibre as due to a biochemical change, possibly the mobilization and reattachment of potassium ions, entailing a momentary loss or reversal of a resting surface-potential at each successive point as the process is conducted in either direction along the fibre by the successive closure of local electrical circuits. When this electrically conducted process reaches the ending of the nerve fibre we suppose that it releases a tiny charge of acetylcholine which during its momentary persistence causes an excitatory depolarization at the surface of ganglion cell or motor end-plate, presumably by a mobilization there of potassium ions, and that the process of excitation is then, as before, electrically propagated along the post-ganglionic nerve fibre or the muscle fibre. It is demonstrable by experiment that when ganglion cells or motor end-plates are treated with curarine they no longer respond to application of acetylcholine or to nerve impulses incident at the synaptic endings but still respond normally to the application of a potassium salt.

This conception, as I said, has not yet won general acceptance. There are those who find it difficult to resign the idea that electrical conduction will suffice to get the excitation across the junctions as well as along the continuous fibres, but they appear thus to become involved in complicated subsidiary hypotheses to account for the special character of transmission at the synapses and for the appearance there, on arrival of nerve impulses, of acetylcholine in a concentration adequate to excite ganglion cells or end-plates. Others, in particular Dr Nachmansohn, have also tried to eliminate the special character of synaptic transmission by supposing that the release and disappearance of acetylcholine provide also the mechanism for the excitatory depolarization at each successive point on nerve

and muscle fibre. They wish to have excitation everywhere cholinergic and everywhere electrically conducted. There is a kind of attraction, especially for some minds, in such comprehensive master-key conceptions. But the proponents of this one have also the formidable task of upholding it against most of the direct evidence. Nobody has been able to show that acetylcholine excites nerve fibres according to the most recent evidence they are as indifferent to it as to cane-sugar, while its excitation of effector and nerve cells first brought it to notice and has become a physiological commonplace. Even the fact that acetylcholine and the enzymes concerned with its formation and destruction are to be found along the course of nerve fibres and are not wholly concentrated at their endings applies only to cholinergic fibres, whereas others conduct impulses by a process not perceptibly different.

I think that it can also be claimed that this theory of the intervention of a special pharmacodynamic phase in the transmission of the excitatory process at these peripheral synapses, and especially from motor nerve endings to muscle end-plates, has already contributed to a better understanding of certain neuromuscular disorders than any which could be offered by the older theory of a uniform electrical mechanism of conduction along fibres and across synapses. On the latter basis we could only discuss whether a particular anomaly was due to abnormal function of nerve or of muscle, and it offered no special explanation for defects at the synapse when excitability and conductivity of both nerve and muscle were normal. There are, of course, conditions affecting nerve fibres or muscle fibres as a whole—the neuritis caused by diphtheria toxin or by other poisons the nerve degeneration and muscular atrophy following the attack of the poliomyelitis virus on anterior horn cells, or other so called muscular dystrophies. None of these, however, are our concern. It is the functional defects or anomalies affecting transmission from motor nerve to muscle without anomaly of conduction in the fibres of nerve or muscle on which the evidence for a chemical mechanism at the junction throws light. Such anomalies may be produced by vegetable alkaloids or bacterial toxins, or by morbid conditions of obscure aetiology.

#### Action of Some Poisons

Perhaps the way in which the chemical theory can add detail and give a specific character to knowledge concerning transmission at a synapse can be most easily presented by considering first the actions of certain poisons. Since Claude Bernard we have known that curare blocks transmission from motor-nerve ending to muscle end plate, leaving both nerve and muscle fibre normally excitable and conductile. On the electrical theory of synaptic transmission we could go no further, curare might stop conduction in the naked nerve terminals or make the end plate inexcitable. Now we know by specific experiments, including those made by Buchthal with minute direct applications to the isolated unit, that curarine blocks the effect on the end-plate not only of an impulse reaching the nerve endings but also, and simultaneously, of the application of a minute quantity of acetylcholine, but leaves the same end plate normally responsive to direct electrical stimulation and to the application of a small dose of potassium chloride. This enables us to conclude that the effect of curarine is to make the muscle end-plate specifically insensitive to acetylcholine and the same can be shown to hold for the ganglion cell when curarine is appropriately applied to it. At the same time it makes clear the danger of applying such terms as "curarizing" or "curare-like" loosely to any action which interrupts or weakens transmission from motor nerve to voluntary muscle. There are obviously several ways in

which superficially similar effects of this kind could be brought about paralysis of conduction in the naked terminal nerve branches, failure of the adequate liberation of acetylcholine from their actual endings either because the depots normally holding it ready there for release are not adequately replenished or because, though full, they do not yield their store when a nerve impulse reaches them, and excess of cholinesterase in such relation to the depots that acetylcholine, though normally released, is destroyed too quickly to produce its full effect. All these should, if possible, be eliminated by experiment before an action is described as "curare-like". An example has recently been provided by the action of the extremely potent toxin of *Bacillus botulinus*. This interrupts the transmission and leaves both nerve and muscle normally excitable like curarine, but experimental analysis in greater detail has shown that the muscle end-plates remain normally responsive to acetylcholine and that it is the release of acetylcholine by nerve impulses which fails. The action is on the nervous side of the synapse, but whether on conductivity in the ultimate branches of the nerve fibres or on the filling or the stability of the depot for acetylcholine still remains to be discovered.

A more complicated problem is presented by the action of tetanus toxin when administered by injection into a muscle in such manner and dosage as to produce a local persistent tetanus of the muscle. As A. M. Harvey has shown, the condition seems to be accounted for by lowering of the retention-level of acetylcholine in the nerve-ending depots and a concomitant loss of cholinesterase from their neighbourhood so that acetylcholine leaks continuously on to the motor end plates, while the arrival of a nerve impulse at the endings elicits only a weak but repetitive twitch from the muscle. When the tetanus is abolished by curarine the muscle responds normally to direct stimulation. It does not seem possible to account for such a condition by any elaboration of the electrical theory of neuromuscular transmission.

It is instructive to note the kind of explanation the chemical transmission theory offers for the previously obscure apparent antagonism between physostigmine (eserine) and a partially paralytic dose of curarine. There seems to be no reason to suppose that physostigmine directly interferes with the depression by curarine of the sensitiveness of the muscle end-plate to acetylcholine. The position seems rather to be that in partial curarization the amounts of acetylcholine making effective contact with the end plates fall below the stimulation threshold for many of these, and for a greater proportion of them with the smaller though normally still supraliminal, charges of acetylcholine which are released by the later stimuli of a series. When physostigmine is given and depresses the cholinesterase in the neighbourhood of the depots it allows the acetylcholine reaching the end-plates again to rise above the stimulation threshold for a larger proportion of them, and even perhaps by its persistence to cause a repetitive response of some and thus still further to raise the total response of the resulting "twitch" towards the normal.

#### Anticholinesterases in Myasthenia Gravis

Probably the best example of the application of the chemical transmission theory to the elucidation of a morbid neuromuscular defect is afforded by myasthenia gravis. It is shown by Blake Pritchard that the response of a myasthenic muscle to rhythmic stimulation of its nerve was very different to that of one which had been partially paralysed by curare. Some years later Mary Waller was led by observations of the alleviation of such effects of curare by physostigmine to try the later and its synthetic analogue,

known by the proprietary name "prostigmin," in the treatment of myasthenia. The evidence for the transmitter function of acetylcholine and for the part played therein by cholinesterase was at the time becoming more generally known. It was natural, therefore, to connect the demonstrated relief of the myasthenic condition by physostigmine and its analogues with the action of these substances—their only common and specific action, indeed—in depressing cholinesterase and thus protecting acetylcholine. More recently other substances, such as disopropyl-fluorophosphate (DFP) and tetramethyl-pyrophosphate, having nothing in common with physostigmine and its more immediate analogues other than a powerful anticholinesterase action, have proved to be similarly effective, and we shall hear more about these later this morning.

It was natural to look for evidence of an abnormal amount of cholinesterase in the blood of the myasthenic, but a number of such attempts failed to produce evidence of significant departure from the normal average in this respect, nor have muscle biopsies given any clearer indication. We seem at present to be left with several possibilities—(1) It is not yet quite excluded that cholinesterase may be abnormally abundant in effective relation to the acetylcholine depots, though failure to find it in excess where it can be measured has rendered this unlikely, (2) there may be a defect of synthesis of acetylcholine and in consequence a defective replenishment of the depots at the nerve endings, (3) the sensitiveness of the muscle end-plates to acetylcholine may be lowered, as in partial poisoning by curarine—it may even be thus reduced by the action of an endogenous curarizing poison.

It will be clear that the remedial effect of the anticholinesterases could be accounted for by any one of these conditions, and thus affords no help in choosing among them. Experiments by Harvey and Lillenthal on the effects on the hand and forearm muscles of injecting acetylcholine directly into the brachial artery at the elbow seemed at first to suggest that the myasthenic muscles had an abnormally high sensitiveness to acetylcholine thus applied, giving a response to it which recalled that of a muscle at an early stage of the degeneration of its motor nerve. If this suggestion had been maintained it would have pointed to a defective storage of acetylcholine at the nerve endings, and thus to the causation of the myasthenia by a defect on the nervous side of the synapse. Later study of these responses has made it doubtful whether the contrast with that of the normal muscle is really of this kind—whether in fact the normal muscle is not more sensitive and in consequence more susceptible to the secondary depressant action of acetylcholine in the large arterial doses in which it was injected. If that were so the condition would be really like a partial paralysis by curare, causing a defect on the muscle side of the synapse, and the provenance of the poison causing it would become a matter of central interest. We could not, of course, overlook the possibility of the production of such a poison by an abnormally persistent thymus, the operative removal of which has been dramatically successful in a good proportion of severe cases of myasthenia though completely ineffective in others. We may hear something on the subject from Dr. Wilson, who has, I know, been examining thymuses removed by operation from myasthenics for the presence of a curarizing poison. Clearly, much more has to be discovered before we can regard the nature of this myasthenic defect as settled, but I do not think I go too far in claiming that the chemical transmission theory has helped to provide a new basis for its investigation.

Another condition, with which Dr. Brown is going to deal, is that of congenital myotonia (Thomsen's disease). I think

that the evidence which Dr Brown will produce will show that the fault in this disease is not so much in the nature of the neuromuscular transmission as in the anomalous response of the muscle fibres to any kind of stimulus, but I do not think it can be doubted that the chemical transmission theory, and the experimental criteria based upon it, assisted a rapid analysis and clear decision in this case also.

Mention should be made also, perhaps, of the recurrent familial paralysis following a large ingestion of carbohydrate, first found by Aitken, Allot, Castleden, and Walker to be associated with a fall in the potassium content of the serum to about one-half its normal value or less and to be promptly relieved by giving potassium chloride. There was no evidence for failure of the excitatory process before it reaches the muscle, which during the paralytic crisis fails to respond to direct electrical stimulation.

### Conclusion

I do not know whether anybody is going to deal in discussion with the recently advocated use of the quaternary tetraethylammonium salts in circulatory hypertension. Many years ago Dr Burn and I pointed out that, whereas the tetramethyl compounds had a powerful nicotine action, their tetraethyl homologues had only a rather weak action of the curare type. Acheson recently confirmed this, emphasizing the fact that, in contrast to curarine, the tetraethylammonium salts depress the responses of the ganglion cells to preganglionic impulses and to acetylcholine more potently than they affect those of the muscle end-plates. If there is reason, then, to attribute a hyperpiesis to excessive outflow of preganglionic sympathetic impulses, tetramethylammonium salts might be expected preferentially to weaken their transmission through the ganglia.

Finally, the question which naturally excites a most urgent interest in the mind of anybody working in this field is that of the extent to which the evidence we have for a chemical transmission at the peripheral synapses provides an analogy for the mode of transmission at synapses in the central nervous system. If we are entitled to assume that cholinergic function at the synaptic endings will be marked by the presence of acetylcholine, and of the power to synthesize it, along the whole course of the fibres concerned, we can apparently conclude that the sensory fibres in the dorsal roots and tracts as far as the first synaptic connexions are definitely not cholinergic. Dr Feldberg and Miss Vogt on the other hand, have been finding by the same criterion evidence for a probable cholinergic function of the secondary neurones. Professor Miller is going to produce evidence of a more direct and functional kind for cholinergic transmission in the synapses of the hypoglossal nucleus and its connexions, and Professor Samson Wright is to deal with the action on central nervous functions of cholinesterases of various types. In the background, as it were, we have Professor Harvey's account of the very remarkable psychopathic effects, of the type of an anxiety neurosis produced in man by continued treatment with DFP in addition to the expected symptoms of excessive parasympathetic effects at the periphery. There is obviously a big field of possibilities here to be explored, and a need for great care and scientific discipline to prevent imaginative speculation from running ahead of the evidence. And we must not forget that, if we accept analogy as indicating even as a working hypothesis, the probability of a chemical mode of transmission at all central synapses, then we must be prepared to look for transmitters other than those already recognized at the periphery and to be on the alert for their discovery.

## FLOCCULATION TESTS: CHEMICAL AND CLINICAL SIGNIFICANCE\*

BY

N F MACLAGAN, D Sc., M D., M R C P., F R I C

*Professor of Chemical Pathology in the University of London at Westminster Hospital Medical School*

The application of the electrophoretic technique to pathological sera has led to the recognition of a relative increase in the serum gamma-globulin content as a fairly frequent event in certain diseases. These can be roughly divided into liver diseases—hepatitis, cirrhosis, chronic passive congestion—on the one hand, and infections on the other. (Longworth, Shedolsky, and MacInnes, 1939, Kelwick, 1940, Gray and Barron, 1943, Olhagen, 1947, Wuhrmann and Wunderly, 1947).

In the infective group the change is particularly prominent in bacterial endocarditis, malaria, lympho-granuloma, and certain cases of plasmocytoma, and probably reflects an increase of circulating antibody. In hepatic diseases it is thought to result from abnormal protein synthesis in the liver. In many of these conditions the demonstration of gamma-globulin excess could have considerable diagnostic and prognostic importance, as it often occurs without alteration of the total globulin level or of the albumin-globulin ratio. However, for technical reasons it is impracticable to rely on electrophoresis for routine diagnostic purposes and we may profitably inquire whether any technical short cut to the required information is available.

The short cuts proposed are of course the so called flocculation tests, and the large number of these that have been invented is perhaps an indication of the need for a reliable method of demonstrating the change in question. There are now at least nine tests that need to be considered. Listed in chronological order they are:

Formol Gel (Galé and Papacostas, 1920)  
Takata-Ara Reaction (Takata and Ara, 1926, Jezler, 1930)  
Weltmann Coagulation Band (Weltmann, 1930)  
Cephalin Cholesterol (Hanger, 1939)  
Colloidal Gold (Gray, 1940, MacLagan, 1944a, 1946)  
Thymol Turbidity (MacLagan, 1944b)  
Thymol Flocculation (Neefe, 1946a, MacLagan, 1947)  
Cadmium Sulphate (Wunderly and Wuhrmann, 1945)  
Sharlach Red (Maizels, 1946)  
Zinc Sulphate (Kunkel, 1947)

Most of these tests were invented on purely empirical grounds some years before their mechanism was understood, and it is only comparatively recently that their common chemical basis has been recognized. Although there are considerable individual variations in the different tests, it is now clear from the work of Gray (1940), Kabat, Hanger, Moore, and Landow (1943), Olhagen (1947), MacLagan and Bunn (1947), and Wuhrmann and Wunderly (1947) that they all become positive in the presence of a sufficient increase in the gamma-globulin fraction, particularly if the albumin is also reduced. The tests are technically simple and rapid in execution, and are capable of yielding results of diagnostic value within a few minutes or hours. In each case the reagent has no pronounced effect on normal serum but produces an easily observable result such as turbidity, flocculation, precipitation, or gel formation with abnormal sera.

\*Based on a paper read to the Section of Physiology and Biochemistry, at the Annual Meeting of the British Medical Association, Cambridge, 1948.

## Chemical Basis of Tests

The chemical factors underlying the various tests are summarized in Tables I and II. Taking first the nature of

TABLE I

Test	Precipitating Agent	pH	Ionic Strength	Serum Dilution Factor
Takata-Ara	HgCl <sub>2</sub>	c 10	0.15	2-16
Formol gel	HCHO	c 8	0.15	1
Cephalin cholesterol	C.C. emulsion	c 8	0.12	26
CdSO <sub>4</sub>	CdSO <sub>4</sub>	c 8	0.10	1
Sharlach red	Sharlach red	c 8	0.075	2-8
Weltmann	CaCl <sub>2</sub>	c 8	0.02-0.002	51
Colloidal gold	Colloidal gold	7.8	0.01	61
Thymol	Thymol	7.8	0.01	61
ZnSO <sub>4</sub>	ZnSO <sub>4</sub>	7.5	0.002	61

TABLE II

Test	Protein Fractions Active		Correlation with Total Globulin	Diseases in which Most Useful
	Precipitating	Inhibiting		
Thymol Gold	γ-globulin γ	Albumin Albumin α and β globulin Albumin	Slight	Hepatitis Hepatitis infections
Cephalin cholesterol	(αβ)γ			Hepatitis
Takata-Ara	(αβ)γ			Liver disease
Formol gel	(αβ)γ		Close	Kala azar
Weltmann short	αβ		?	infections
long	γ			Lung
CdSO <sub>4</sub>	(αβ)γ		?	infections Infective hepatitis

the precipitating agents, these consist of salts of divalent metals (CaCl<sub>2</sub>, CdSO<sub>4</sub>, HgCl<sub>2</sub>, ZnSO<sub>4</sub>), organic protein precipitants (formaldehyde and thymol), or negatively charged colloidal solutions (gold, cephalin cholesterol, sharlach red). In the first two groups it is noteworthy that very low concentrations of reagent are employed, much lower than those ordinarily used for protein precipitation. In the case of the colloids the negative charge on the colloidal particles is unexpected in view of the similar negative charge on the protein under the conditions of the test. Evidently the reaction here is not merely one of mutual charge neutralization but must depend upon chemical differences in protein structure. As regards ease of preparation, the gold and cephalin-cholesterol reagents have given rise to certain difficulties and occasional discrepancies between the results obtained in different laboratories, but all the other reagents are easy to reproduce. A simplified method for preparation of the gold sol has recently been published (MacLagan, 1946).

The pH and ionic strength of the medium are all-important in these tests, and it will be seen that they all proceed in weakly alkaline solution—pH 7.5 to 10—and at low ionic strength (0.15-0.002). The striking effect of altering these two variables is particularly evident in the gold and thymol tests, which both work best at pH 7.8 and ionic strength 0.01 (MacLagan, 1944a, 1944b). These tests become quite unselective if carried out at, for example, pH 6 or at higher ionic strength, so that it is evidently desirable to exert an accurate control of pH with buffer solutions. This has been done in the gold and thymol tests but not in any of the others. Incidentally it is doubtful whether any buffer of much lower ionic strength than 0.01 would be efficient, and this level appears to be about the lowest compatible with accurate pH regulation. Thus the buffer proposed by Kunkel (1947) with an ionic strength about 0.001, is probably too weak to exert a decisive influence on the pH of the reaction mixture.

The serum dilution factor is important and is intimately connected with the last two variables. It has varied from 1 to 61 in the various tests, but the more successful ones employ a high dilution factor. Considerable dilution is in

any case necessary if the test is to proceed in a buffered solution at low ionic strength, so as to avoid interference from serum electrolytes. Thus the ionic strength of serum is about 0.15 and its bicarbonate content of 0.03 M buffers it to approximately pH 8 when exposed to the atmosphere, a sixtyfold dilution therefore permits reasonably accurate buffering at any desired pH at ionic strength 0.01 if a monovalent buffer such as barbitone is used.

## Electrophoretic Data

I have already mentioned the common factors of gamma-globulin and albumin which are concerned with all the tests. Table II summarizes the facts so far collected about the protein fractions active in the various tests by the workers already mentioned, and it will be seen that there are certain individual differences. Thus certain alpha and beta fractions are concerned with the cephalin-cholesterol, Takata-Ara, and formol-gel tests, while these alpha and beta fractions definitely inhibit the gold test. The thymol test appears to be simplest, since it depends only upon the albumin and gamma fractions. The Weltmann CaCl<sub>2</sub> test is really two separate tests, for according to Olhagen (1947) the shortened band indicates alpha- or beta-globulin excess while the lengthened band indicates gamma-globulin excess. Only the latter is therefore analogous to the other tests considered.

Although the data are scanty at present there are evident indications that qualitative changes in the electrophoretic fractions are important. Thus MacLagan and Bunn (1947) found that only the gamma-globulin separated from hepatitis serum produced flocculation with the thymol reagent, normal gamma-globulin gave a turbidity but no flocculation. Similarly in this work it was shown that only the hepatitis (alpha plus beta) fractions precipitated the cephalin-cholesterol and Takata reagents, normal alpha and beta fractions did not. There were also differences in the albumin fractions, normal albumin inhibiting the thymol turbidity test while hepatitis albumin did not. Similar differences in the inhibitory power of albumin fractions from different patients were noted by Guttman *et al* (1947) and Moore *et al* (1945) in a study of the cephalin-cholesterol test.

In apparent contradiction to the work on the thymol test discussed above are the results of Cohen and Thompson (1947) and Kunkel and Hoagland (1947), showing a fall mainly in the beta-globulin content of sera treated with the thymol reagent. However, since it is generally agreed that isolated beta fractions do not react with thymol, the significance of this observation is open to doubt. It may well be that the thymol removes phospholipid from the beta fraction and so produces an apparent fall in the beta-globulin. It is in fact well known that the presence of phospholipids is essential to the thymol reaction and that they are associated mainly with the beta-globulin fraction. Nevertheless, while isolated gamma-globulin plus phospholipid (or plus beta-globulin) will give a turbidity with thymol, isolated beta-globulin either alone or with added phospholipid has not done so in any experiment so far reported. It would appear therefore that the gamma-globulin is the important fraction and that the beta fraction acts only by contributing phospholipid.

As a corollary to this, occasional sera with grossly excessive lipid content may give "false" positive reactions with thymol. These can be detected by raising the ionic strength of the thymol buffer (Kunkel and Hoagland, 1947). The addition of 5% w/v of NaCl is convenient. This will abolish reactions due to gamma-globulin and will not affect those due to lipaemia.

## Correlation with Total Serum Globulin

The last two columns of Table II summarize certain features which are further illustrated in Figs 1-6. Since the tests aim at demonstrating excess of a particular type

FIG 1

of globulin it is obviously important to compare them with the total globulin estimation. The figures also illustrate the relation of the various tests to liver diseases, the hepatitis cases being shown as dots in circles and the other diseases as dots.

Taking first the formol-gel test (Fig 1), it will be seen that all positive cases have total globulin values over

FIG 2

FIG 3

31 g per 100 ml, and there is no particular relation to hepatitis. This test therefore has little advantage over the total globulin estimation except that of technical simplicity. It would appear from Kunkel's (1947) report that similar remarks apply to the new ZnSO<sub>4</sub> test, although observations on this test in non-hepatic conditions are not yet available. The other tests on which similar data are available (Figs 2-6), however, show the exact opposite—namely, a predominance of positive results in hepatitis and little correlation with total globulin. Mawson's (1948) figures for

FIG 4

FIG 5

the Takata-Ara reaction (Fig 2) are not quite comparable with the others, as they refer only to jaundiced patients. It is, however, evident that with this test positive results are frequent in obstructive jaundice—i.e., in the absence of hepatitis.

## Value as Liver Function Tests

The relative merits of the various tests can now be discussed, taking first their value as liver function tests. It is evident from Figs 1-6 that the thymol, gold, and cephalin-cholesterol tests are valuable indicators of hepatitis.

as most of the positive results were recorded in this condition. Some typical reports are summarized in Table III from which it will be seen that the sensitivity

TABLE III—Incidence of Positive Results in Liver Disease (% Positive)

Disease	Thymol	Gold	Cephalin Cholesterol	Takata Ara
Infective hepatitis	91-99 <sup>1</sup>	92 <sup>2</sup>	66-94 <sup>3</sup> 100 <sup>4</sup>	84 <sup>6</sup>

Obstructive jaundice	8 <sup>5</sup>	8 <sup>5</sup>	16 <sup>3</sup> 17 <sup>4</sup> 78 <sup>7</sup>	41 <sup>6</sup>

<sup>1</sup> Gray (1940) <sup>2</sup> Hanger (1939) <sup>3</sup> Jezler (1930) <sup>4</sup> Kirschner and Glickmann (1943) <sup>5</sup> MacLagan (1944b) <sup>6</sup> Mawson (1948) <sup>7</sup> Pohle and Stewart (1941)

<sup>8</sup> Shank and Hoagland (1946)

of these tests in infective hepatitis and hepatic cirrhosis is very high, being in the neighbourhood of 90-100% in most of the series quoted. The proportion of positive results in post arsphenamine jaundice is, however, much lower, being only 47% in the case of the gold and thymol tests (MacLagan, 1944b, 1944c). It seems that a similar preponderance of negative results is found in homologous serum jaundice (Neeft, 1946b), and this difference fits in

The other tests mentioned seem to be less useful in the diagnosis of liver disease, although reports are in some cases conflicting or incomplete. It is claimed that the Sharlach-red test gives results very similar to the gold test (Maizels, 1946, Ducci, 1947), and the CdSO<sub>4</sub> test has found some application in hepatitis (Wuhrmann and Wunderly, 1947). The large literature on the Takata-Ara reaction was reviewed by Magath (1940). The CaCl<sub>2</sub> test has found most application in non-hepatic conditions.

#### Value in Non-hepatic Conditions

All the tests tend to give positive results in infections of the type mentioned above, and such results may often be of diagnostic value. Thus the formol-gel test has been found useful in kala-azar (Napier, 1921), and the Takata-Ara reaction was originally used in pneumonia, in which it was said to help in differentiating lobar pneumonia from bronchopneumonia (Takata, 1925). The Weltmann test is said to indicate "exudative" or "fibrotic" changes, and has been particularly employed in lung infections in a manner rather similar to the sedimentation rate (Gradwohl, 1943). The CdSO<sub>4</sub> test has also been applied in this field.

Results of this type are perhaps less frequent with the gold, thymol, and cephalin-cholesterol tests, but they are by no means absent, and the gold test in particular has given a high percentage of positive results in heart failure, malaria, infective endocarditis, glandular fever, and rheumatoid arthritis (Carter and MacLagan, 1946). The cephalin-cholesterol test is also usually positive in malaria (Fredricks and Hoffbauer, 1945) and the thymol test in glandular fever (Cohn and Lidman, 1946). Such results can be of diagnostic help—for example, in a case of febrile rheumatic carditis with infective endocarditis as a possible complication positive flocculation tests would favour the graver diagnosis. In the infective group as a whole the tests probably depend mainly on antibody production and give easy and rapid evidence of this process. In heart failure, glandular fever, and possibly malaria, on the other hand, they probably reflect a true hepatic involvement in the disease and may have some prognostic value, particularly in heart failure. The unexplained high proportion of positive gold tests in rheumatoid arthritis is entirely different from the mainly negative findings in spondylitis ankylopoietica, and forms a useful point of distinction between these two diseases (Hart *et al.* 1948).

The possible application of the tests in protein chemistry and in immunology has been little explored. If they can detect differences between protein fractions which are electrophoretically identical they must have some contribution to make to the characterization of proteins in general. Thus they have already been able to show differences between all the electrophoretic practices obtained from normal and hepatitis sera respectively. In this sense they may form a useful addition to the electrophoretic method.

#### Discussion

The principal result of the work which has been reviewed here is that this group of tests can now be seen as a whole and an attempt made to assess their value. It would seem that they are now entitled to be lifted from the realm of doubtful and mysterious procedures to the status of practical short cuts to the demonstration of a particular type of protein change in the serum. This may be described as a relative gamma-globulin excess, and the finding is of great diagnostic help in hepatitis and is of theoretical interest in various infective conditions. The possible clinical value in infections needs to be explored by further study. The information obtained from the tests is additional and complementary to the usual serum protein estimations, and the

FIG 6

well with the very definite immunological difference that has been demonstrated between infective hepatitis and homologous serum jaundice, which are now thought to be due to different viruses (Neeft, Stokes, and Gellis, 1945). The Takata-Ara reaction gives somewhat similar results to the others in cirrhosis, but has not been so widely used in acute hepatitis.

The results in obstructive jaundice are, however, very different with these four tests, thymol and gold giving mainly negative results, while cephalin cholesterol and Takata-Ara are often positive (16% to 78%). This gives a definite advantage to the thymol and gold tests for the special purpose of investigating jaundice of doubtful origin, in which they have proved very useful (MacLagan, 1944c).

The detection of residual hepatitis after an acute attack is an example of where the thymol test has found particular application as shown particularly in the work of MacLagan (1944c) who found that the thymol flocculation test was positive for as long as a year after an attack of hepatitis being associated in this case with residual jaundice and positive evidence of hepatic damage.

proportion of positive results in the conditions indicated is in general much higher than the incidence of high total globulin values or of changes in the albumin-globulin ratio. On account of the non specific nature of the tests they must always be interpreted with due regard to the general clinical background, a proviso which would of course apply to most laboratory investigations.

As regards the relative merits of the various tests there is room for considerable difference of opinion. However, from the physico-chemical angle it can be said that the conditions are more accurately controlled in the case of the thymol and colloidal-gold tests, in which the pH and ionic strength are kept at optimum levels by means of buffer solutions. Study of purely clinical data suggests that the gold, thymol, and cephalin-cholesterol tests all have certain advantages, but in the study of liver disease the thymol test appears at present to be slightly superior. It also has the advantage that the reagent is easier to prepare than either of the other two. Most of the other tests mentioned are probably not so reliable as "liver function tests" but have found useful applications in the study of certain infections. The position of the shalch-red and zinc-sulphate turbidity tests needs to be elucidated by further study.

There is a certain advantage for routine purposes in using two tests of slightly different character, and my present preference is for the thymol (turbidity and flocculation) and the gold tests. The former is fairly specific for liver disease, the latter gives a greater sensitivity in conditions such as rheumatoid arthritis. However, the gold test might well be replaced by the cephalin-cholesterol test or possibly one of the other tests if difficulty is experienced in making up the gold sol. All the tests are so similar in principle that it is to be hoped that some degree of standardization will be eventually achieved, the ideal would be a single accepted test for demonstrating gamma-globulin excess.

### Summary

The chemical mechanism underlying the various flocculation tests has been considered, and the essential similarity of these tests is emphasized.

All the tests are influenced positively by serum gamma globulin and negatively by albumin. The alpha- and beta-globulin fractions do not influence the thymol test but have a variable effect on the others.

The formol-gel and ZnSO<sub>4</sub> tests are closely correlated with total serum globulin, the others have little correlation with total globulin.

The relative value of the various tests as indicators of hepatic dysfunction and of antibody formation is discussed.

## THE CONSERVATIVE TREATMENT OF PLACENTA PRAEVA

BY

W G MILLS, FRCS, MRCOG

Late RSO Birmingham Maternity Hospital

In every discussion on the treatment of placenta praevia there are two fundamental questions to be answered—namely, what to do and when to do it. The former has fortunately been simplified with the increasing safety of the lower-segment caesarean operation, and the procedure of choice will usually be either rupture of membranes or abdominal delivery. However, the optimum timing of this intervention remains a matter of opinion on which authorities are at variance. It has long been taught, with considerable emphasis in many schools, that expectant treatment of a diagnosed or suspected placenta praevia can never be countenanced. This principle has been based upon the not unnatural supposition that a patient with a major degree of placenta praevia would in the absence of intervention frequently bleed to death, and that fatal haemorrhage might ensue at any time without warning. Evidence is accumulating, however, to suggest that more tragedies are produced nowadays by overtreatment than by neglect, and that in some cases delay might even benefit mother as well as foetus, for in the borderline case rupture of forewaters can be performed with far more confidence when it has been possible to delay until the uterus is contracting and the cervix open.

An American obstetrician (Johnson, 1946), in an enthusiastic overstatement to prove his case, has promised a reward for records of any case of placenta praevia in which death from haemorrhage has followed strict non intervention in all stages of labour. It has apparently not been claimed, but this does not necessarily prove anything, since no doctor could remain idle in expectation of seeing his patient die from haemorrhage. This helps to emphasize the fact that there are natural ways of arrest of haemorrhage from a placenta praevia. In rare instances the placenta may actually be delivered spontaneously in front of the foetus with remarkably slight blood loss (Lloyd, 1947, reported below). It cannot be denied that some cases of placenta praevia have sudden haemorrhages which may be most alarming and require urgent blood transfusion if the uterus is not emptied as a routine as soon as the condition is suspected. On the other hand, a period of delay might facilitate treatment and decrease the number of caesarean sections, and it assuredly will lower the appalling foetal loss from prematurity.

A brief review will be given of the recent pertinent literature and a series of 100 cases presented in an effort to assess the advantages and risks to mother and child that may be expected with conservative treatment

### Recent Literature

Probably the finest series of cases in which treatment was based strictly on the old principle of immediate intervention was reported from Chicago by Davis and Campbell (1946). Treatment was generally confined to caesarean section or rupture of the membranes according to the position of the placenta as felt on vaginal examination shortly after the patient had been admitted to hospital, maternal mortality was as low as 0.6% (two deaths in 325 cases), which compares extremely favourably with the figure of 5.9% compiled by Professor F. J. Browne (1946) from 3,103 cases in recent records of 11 British teaching hospitals. The caesarean section rate was 40%, and blood transfusion was given to 40% of patients (a high figure). Quoting a foetal mortality of 32%, the authors state that "the most important cause of foetal death was prematurity," and "the premature infant has been considered expendable to ensure the greatest possible safety for the mother." Although this figure for foetal loss is decidedly better than that of 54.2% in Browne's series, it is not nearly low enough, and other authorities claim that judicious conservatism will give equally good maternal results with considerably improved chances for the baby.

Expectant treatment was championed simultaneously on both sides of the Atlantic by Macafee (1945) and Johnson (1945). Both based their treatment on the contention that in the absence of vaginal manipulation the first haemorrhage from a placenta praevia will never be fatal, and subsequent haemorrhages will not be fatal so long as the haemoglobin level of the blood is normal at the onset of bleeding. Macafee reported a personal series of 174 cases with one death and a foetal loss of only 23.5%, yet this figure included six foetal abnormalities and nine other cases in which the low implantation of umbilical cord into placenta made foetal death almost inevitable after a severe haemorrhage. An improved figure for foetal loss of only 6% was achieved in the last 47 cases. This revolutionary conception of foetal risk was attained by extreme conservatism: the principle was laid down that no vaginal examination should be made unless and until it could be followed immediately by whatever treatment was required for delivery (e.g., caesarean section). Thus a patient would be put to bed to wait until the last few weeks of pregnancy, regardless of repeated "warning" haemorrhages so long as there was no undue anaemia, and with increasing experience there was less cause for alarm over any one apparently severe attack of bleeding. Macafee states significantly that "among these patients there has been nothing to confirm the belief that recurrent haemorrhages tend to lead up to one catastrophic haemorrhage." He permitted a period of delay in over half the cases, one patient spending 14 weeks in bed while another had nine attacks of bleeding, yet blood transfusion was required in only 13% of patients, and 33% (not a high figure) were delivered by caesarean section.

Johnson (1945) treated 79 cases of placenta praevia with one maternal death and with loss of 22% of babies. His high (53%) caesarean section rate is an index of his reluctance to interfere vaginally in any way at all, and his statement "a non-traumatized placenta praevia will not bleed" sums up his general attitude. To check the validity of Macafee and Johnson's conclusions, Yepes and Eastman (1946) summarized 14 cases that had been treated during the past

half-century along conventional lines in the Johns Hopkins Hospital. The maternal mortality had been reduced during the period from 13.8% to 0.9%, but the foetal loss had improved only from 78.5% to 46.8%. They found that in no instance had an initial or subsequent haemorrhage been the cause of death except in association with extensive vaginal manipulation, and that the only patient to die undelivered (in 1920) had refused treatment, had become profoundly anaemic from four subsequent attacks of haemorrhage at home, and had finally died after vaginal manipulations.

Daichman and Pomerance (1947) reported a series of 165 cases over an eleven-year period, with one maternal death and a foetal loss of 26%. They attribute their good results to a rather liberal use of caesarean section (59%) and a gradual increase in expectant treatment. They consider that it is safe to temporize "when the infant is near viability," implying that repeated haemorrhage is less likely to occur before the last few weeks of gestation; this may not be altogether true, but it serves to underline their approval of at least a limited conservatism.

Finally, Williams (1948) reported a series of 105 cases with only one maternal death over an eleven-year period, the foetal loss was 28% and the caesarean section rate 42%. However, there were 41 cases (39%) treated expectantly, and of these the foetal mortality was only 12%. He thus endorses the great improvement in foetal chances of survival that may be expected with this treatment.

After such apparent success of varying degrees of conservative treatment it was disappointing to hear reactionary views from Scotland expressed by Sturrock, Stirling, and Tennent (1947). A series of 228 cases was quoted from Edinburgh with only two maternal deaths but a foetal loss of 39%; conservative treatment had been practised in 6%, and the authors express no enthusiasm for it on account of "the close vigilance required and the smooth and speedy application of appropriate treatment essential in the presence of the sudden further haemorrhage." The Glasgow school, quoting 505 cases, in 27% of which there had been at least 24 hours' delay before instituting active treatment, was very discouraging: the overall figures showed 18 maternal deaths, 34% foetal loss, and 55% caesarean sections, while in the delayed group there was a slightly higher foetal loss with considerably greater maternal morbidity. The significance of these results may perhaps be offset by the selection of their group for delayed treatment, so that direct comparison of results between the two groups is not applicable. Another factor that might have affected the expectant group adversely is a variation from the more usual management of this type of case: vaginal examination of the more serious cases was conducted under anaesthesia in only 1 or 2% of patients.

To conclude this summary of available evidence it may be stated that most of the obstetricians who have reported their experiences of the expectant treatment of placenta praevia appear to have been favourably impressed with the results.

### Personal Experience

In the following report a small series of cases has been analysed in an attempt to ascertain how nearly the results of Macafee and Johnson can be equalled in a busy hospital in which responsibility for emergencies devolves upon all members of the honorary staff. It is obvious that the principles of conservative delay (with its worries and disadvantages) are unlikely to be accepted as quickly and comprehensively as when all experience is gained and all responsibility accepted by one man. It is therefore encouraging to record a consecutive series of 100 cases of placenta praevia (95 in 1947 and 5 in 1948) treated at

the Birmingham Maternity Hospital by six members of the staff with no maternal deaths and the loss of only 17 out of 103 babies (stillbirths and neonatal deaths in hospital). There had been no maternal death from placenta praevia in the three years prior to this series.

The principles of treatment were as follows. There was general agreement among the staff that so far as possible no infant should be delivered before about the 37th week of gestation, although, if the foetus appeared to be very well developed and there were other indications, a week or two earlier might be allowed. After the 37th week it was considered that the risks to the foetus of asphyxia following a severe haemorrhage, and the now unnecessary loss of blood to the mother outweighed the advantages of the last few possible weeks *in utero*, consequently a severe haemorrhage in the last three or four weeks was considered an indication to empty the uterus before this it called for conservative treatment. However, there was considerable divergence of opinion among the staff about the wisdom of continued delay in the face of repeated haemorrhage, and inevitably there were occasions on which active intervention was deemed advisable in maternal interests when another surgeon might have advised procastration still further.

The usual procedure in the case of haemorrhage before the 37th week was to admit the patient to hospital, examine the cervix with a speculum, give morphine as required, and wait for bleeding to stop, the haemoglobin level was checked, the blood grouped and the rhesus test performed, and blood cross matched for transfusion in the more serious cases. After several days without further loss primigravida patients were often sent home to bed and most cases with only a slight loss before the 32nd week were allowed up and sent out with instructions that in the event of further haemorrhage they should go straight to bed and discourage any vaginal examination. No attempt was made at radiographic diagnosis of the placental site. No vaginal examination was to be made in hospital until the formal procedure under an anaesthetic with the theatre set for caesarean section generally after the 36th week. The date of this examination depended on the size of the baby, the recurrence of haemorrhage, and the attitude of the surgeon to repeated blood loss and also on the reaction of the foetal heart to each attack of haemorrhage. As a general rule the procedure adopted was caesarean section for cases in which the placenta was palpated across the cervix or coming up to its margin (the second, third, and fourth degrees of Professor F J Browne) with rupture of membranes for the others. Sometimes a second degree case in a multipara would be treated by rupture of membranes with application of Willett's forceps to the scalp, or bringing down a leg of a flexed breech if this could be done easily through a dilating cervix, thus one would be able to exert traction on the presenting part should the bleeding be uncontrolled. Bipolar version and subsequent breech extraction was employed only twice, on patients whose babies were already dead.

The anaesthetic for the examination was generally thiopentone and it was usually followed by gas-oxygen-ether or 'trilene' for the section a number of severe cases in which the diagnosis appeared self-evident, however were operated on under spinal or local analgesia without any vaginal examination in an effort to avoid further foetal distress. The lower-segment operation was generally used. Blood transfusion was given freely being set up before the vaginal examination in all cases of dangerous haemorrhage. It was used in 21 cases including three occasions for post-partum haemorrhage following vaginal delivery. Statistics are given in Table I.

### Conservative Treatment

Macfee quotes a figure of over 50% for cases of placenta praevia in which conservative treatment was practicable. This was by no means so in the series under consideration. There were two reasons: in the first place the majority of patients had already experienced one or more attacks of bleeding before admission and successful (though often ill advised and hazardous) conservative treatment had been practised by their practitioners; consequently the majority of those admitted were already in the last month of pregnancy. Secondly a distressingly large number of patients had already been examined

vaginally outside hospital, and this misplaced active intervention had often produced serious exacerbation of haemorrhage and sometimes foetal distress. There were in fact only 26 patients (27 babies) admitted with bleeding before the 36th week, and as one patient was already in labour and two babies were dead there were only 24 cases in which it is considered that planned conservative treatment was possible. These are summarized in Table II.

TABLE I—Statistical Summary

Cases of placenta praevia	100
Babies delivered	103
Maternal deaths	0
Foetal and neonatal loss	17 (16.5%)
Types of placenta	
1st degree	43
2nd	28
3rd	25
4th	4
Primigravidae	32
with 1st degree placenta praevia	19 (59%)
Treatment	
Caesarean section (including 2 following A R M)	47

persisted for over 7 days	16 (3)

### Maternal Prognosis

The maternal prognosis under the conservative regime has not apparently deteriorated in any way, and in very few cases was there ever cause for the slightest alarm, this may have been partly due to a natural reluctance to continue procastration in the face of repeated bleeding, but the morale of the resident staff, as well as the safety of the patients, was certainly maintained by a good supply of readily available blood for transfusion. On several occasions there was a sudden loss of 15–20 oz (425–570 ml) of blood, usually in the middle of the night, but experience soon confirmed Macfee's statement that these haemorrhages are not catastrophic. In fact it can be categorically stated that in no instance was maternal life endangered by conservative treatment: there were no deaths and no near deaths. In the 16 cases in which conservatism was practised for a week or more, in hospital or after discharge home, the maximum period of delay was 8 weeks and the average 17 days. Of the four cases in which active treatment was adopted in less than a week two had recurrent haemorrhage, one had pre-eclamptic toxæmia, and one had spontaneous premature labour.

### Foetal Prognosis

The reduction of foetal loss is the real justification of conservative treatment, and the figure of 16.5% compares favourably with F J Browne's collected figure of 54% and with other series where active intervention has been adopted. That the improvement chiefly affects the premature component of the foetal death rate is shown by the 24 quoted cases in which the patient was admitted before the 36th week and conservatism was possible: when it was practised the loss was 15%, and when it was neglected the loss was 75%. The whole subject of foetal death in relation to placenta praevia is so important that an analysis has been made of the cases in this series and an effort has been made to determine how far foetal

TABLE III—Analysis of the 17 Foetal Deaths

Associated with prematurity	6
Possible mismanagement	1
Misfortune	1
Apparently inevitable	5

mortality may be reduced by conservative strategy and skilled tactics and what may be the hard core of inevitable loss. Table III gives a rough classification of the 17 cases.

In any discussion on the inevitability or otherwise of foetal death it is essential that outside practitioners and hospital staff should be considered together as one therapeutic unit. In no

case should loss of a baby be classed as inevitable on the grounds that the damage was done before admission to hospital, and it is only by a consideration of the mistakes of the practitioners, as well as the possible accidents or errors committed inside hospital, that a true estimate of optimum foetal prognosis may be made.

There were six foetal deaths associated with prematurity, and four of these patients had had vaginal examinations which had precipitated further bleeding before admission, in one case the foetus was dead on admission and in another the patient was already in labour, though it is difficult to be certain how far these facts are attributable to intervention. In the other two cases which had already been examined it was decided that conservative delay was unlikely to be successful, and both were examined under anaesthesia, followed by section for one and rupture of membranes for the other. Of the two patients who had had no intervention, one was kept in hospital for two weeks (29th to 31st) and then delivered because of repeated minor haemorrhage, the other (at the 34th week) was delivered at once. Both had caesarean sections and both infants died as the result of prematurity. It is probable that if intervention had been longer delayed the chances of survival of these two infants would have been materially increased, with little if any, added maternal risk.

It is unfortunately necessary to record five cases in which foetal death followed mismanagement in some stage of the patient's treatment either by the practitioner outside or by the resident staff in hospital. The first, a 3-gravida with no living children, had four "warning" haemorrhages in the last month of pregnancy before a final severe bleeding for which she was admitted in labour at term, there was profound foetal asphyxia, and despite immediate caesarean section the child failed to survive. At operation it was found that the cord was inserted into the placenta immediately over the internal os. This case serves to emphasize that in the last weeks of pregnancy conservative treatment may not be in the interest of the foetus. The second case illustrates the same lesson. A 2-gravida was admitted following an initial severe haemorrhage at the 38th week. There was no foetal distress, and examination was delayed on account of other supposedly more urgent work, but three hours later the foetal heart rate fell to 104 and caesarean section, though urgently performed failed to save the child, it lived for a few hours, and necropsy showed severe asphyxial changes in the viscera. The third case (reported elsewhere, Mills, 1948) was one of vaginal delivery of a multipara despite a third degree placenta praevia. Premature rupture of membranes without bleeding had led to the erroneous conclusion that the os must be at least partly covered by membranes, and the patient was delivered by traction on Willett's forceps, which controlled bleeding but asphyxiated the baby. Finally, there were two cases in which bad technical errors were made. A baby was lost from cerebral haemorrhage during forceps extraction at the 36th week following two weeks' successful conservative treatment of a primigravida, and a foetus died from asphyxia in the first stage of labour owing to compression of a posterior placenta praevia by the descending head in a primigravida patient in whom placenta praevia had not been suspected. These five cases represent five unnecessary foetal deaths.

The one case of "misfortune" was an 8-lb (3.63 kg) baby which died from neonatal infection when a fortnight old.

There were five cases in which foetal death appears to have been unavoidable. Two of these were cases of vasa praevia, in one of which only the first of twins was lost, while in the other there was no haemorrhage until the presenting vessel was torn with the rupture of the membranes early in labour. There was one hydrops foetalis. One case appeared to be an association of placenta praevia with accidental retroplacental haemorrhage and rapid foetal asphyxia. The final case (reported elsewhere, Lloyd, 1947) was one in which the placenta became fully separated early in labour with no alarming haemorrhage and was found lying loose in the vagina at examination for an impacted shoulder presentation.

There is thus reason to believe that with good luck, more skilful management and a more resolute adoption of conservative principles the foetal loss in the cases outlined above might have been reduced from 17 to 7 without in any way increasing the maternal dangers.

## Conclusions

The number of cases of placenta praevia in which it is possible and advisable to adopt conservative measures depends upon the stage in pregnancy at which the patient is sent to hospital for advice. If this is sought after the first haemorrhage, and there has been no previous intervention, Macafee's experience shows that deferring of active treatment may be practicable in over 50% of cases, but if, as is shown in this series, there has already been procrastination or examination before admission, then this number may be reduced to about 25%.

Conservative treatment has advantages and disadvantages for the mother, the latter are the more obvious. She must either be confined to hospital or lead a very restricted existence at home for a number of weeks, and she may sometimes be required to suffer further haemorrhage, on the other hand, there is little, if any, increased danger to life, and there is a slightly lower chance of the need for delivery by caesarean section. If, however, caesarean section should eventually become necessary there is a much greater probability that she will get a live baby in compensation.

The advantages to the foetus of conservative delay greatly outweigh the risks, since maturity is the prime requisite for foetal survival. However, it must not be forgotten that any serious haemorrhage may suddenly produce foetal asphyxia and consequently delay of even a few hours is unjustifiable when the foetus has reached a satisfactory stage of development. Since conservative treatment has been adopted for placenta praevia the published reports show for the first time a foetal and neonatal loss below 30%.

Finally, it is considered that the careful adoption of conservative measures in suitable cases is practicable only in a hospital serving an area blessed with reasonably good transport facilities, a good blood-transfusion service, and an adequate standard of general nutrition among its patients, further, it will naturally require a sufficiency of antenatal beds and an experienced resident staff. In these circumstances, given co-operation from the local practitioners, there is every opportunity for the reduction of foetal mortality in placenta praevia to a figure in the region of 10% while the maternal mortality remains at its present minimal figure.

## Summary

Recent literature relative to the conservative treatment of placenta praevia is reviewed.

A series of 100 cases of placenta praevia treated largely along conservative lines is reported, there were no maternal deaths, and the foetal and neonatal loss was 16.5%, which compares favourably with other recently reported figures.

The causes of foetal death in this series are analysed, the majority would appear to have been avoidable.

Conclusions are drawn regarding the present scope of conservative treatment.

My thanks are due to Professor Chassar Moir for helpful criticism and advice, to Miss P. Challons for assistance with hospital records, and to the honorary staff of the Birmingham Maternity Hospital for permission to publish their cases.

# THE DIAGNOSIS OF LATENT TETANY WITH OBSERVATIONS ON THE EFFECT OF CALCIFEROL

BY

D K O'DONOVAN,\* MD NUI, Ph D McGill

Visiting Physician St Vincent's Hospital Dublin

(From the Department of Physiology University College and  
St Vincent's Hospital Dublin)

The object of this publication is to call attention to some pitfalls in the diagnosis of latent tetany and to show that the usual diagnostic methods are inadequate. A more detailed account of a new hyperventilation test which was mentioned in a preliminary communication (O'Donovan, 1945) is included.

The 34 patients studied were adults and adolescents, and almost all had chronic latent tetany. This may be important, as most writers on the subject deal with children and with acute or transient tetany. All the patients in this series had hypocalcaemia—i.e., less than 9 mg per 100 ml of serum calcium. With the method used (Clark and Collip, 1925) the normal serum calcium varied from 9.5 to 11.5 mg per 100 ml, but it is fairly reasonable to presume that figures between 9 and 9.5 mg are not definitely abnormal. Hypocalcaemia is here assumed to be synonymous with latent tetany, as none of the patients had renal disease or any gross abnormality of their serum protein. If the methods of diagnosis of latent tetany in hypocalcaemia are reliable they should also be reliable in other causes of latent tetany.

It will be noted from the Table that the number of observations exceeds the number of individual patients, since patients were usually seen at intervals of six to twelve

## Tests for Latent Tetany on Hypocalcaemic Patients not Receiving Calciferol

	No of Patients	No of Observations	No of Positive Reactions	Positive	Negative
Chvostek's sign	30	85	23	27%	73%
Trousseau's sign	32	89	59	66%	34%
Combined test	13	27	23	85%	15%
Trousseau's sign and the combined test where necessary	32	58	55	95%	5%

months. Only one observation was recorded when a patient was studied daily for some days and there was no gross change in serum calcium or signs of latent tetany.

The patients' hypocalcaemia was due to surgical hypoparathyroidism (14 cases), apparent idiopathic hypoparathyroidism (2 cases), or calcium deficiency (18 cases). The last-named were mostly cases of idiopathic steatorrhoea, although dietary deficiency may have influenced some. When patients were given calciferol (50,000 to 100,000 units daily) the calcium intake was kept at an approximately normal level by instructing them to take half a pint of milk daily in addition to the usual diet.

## Signs of Latent Tetany without Calciferol Therapy

Erb's sign of electrical excitability is not considered here, as it is not a feasible procedure in ordinary clinical examinations. It is unreliable in minor degrees of latent tetany in which an improved method of diagnosis is needed. It is also not so objective and clear-cut as some descriptions would lead us to believe.

Chvostek's sign is so unreliable that its sole merit is its convenience. In only 27% of observations (see Table)

\*Assisted by a grant in aid from the Medical Research Council of Ireland.

was it found positive. If it has any value it is in recent or acute tetany, as it was observed to be strongly positive in 9 out of 11 cases of hypoparathyroidism within three days after thyroidectomy. It is considered that when the tap on the facial nerve causes contraction around the mouth, nose, and eyes (+ 3 response) there is very satisfactory evidence of latent tetany and biochemical investigation is indicated. A negative or trace reaction involving the upper lip is of no significance, and should not exclude the other clinical tests for tetany.

## Trousseau's Sign

This was found positive in 66% of observations (see Table). It is very dependable, as it is rarely positive in normal subjects. It is, however, sometimes positive in people of a hysterical type or in workers whose hands are held in a semi-tetanic position for some hours daily—e.g., seamstresses, cobblers, and glove or leather stitchers. Another source of error may be avoided if the test is always done on the arm that is more often used, as it is rarely positive on that side only (O'Donovan, 1945).

The technique of Trousseau's sign is seldom described adequately. The tourniquet should be applied at greater than systolic blood pressure so that the radial pulse is obliterated. This should be checked during the test. The tourniquet should be applied without painful nipping of the skin, and a sphygmomanometer is therefore advisable. For a very obese or heavy muscular arm a pressure pad may be applied on the brachial vessels and nerves. The presence of carpal spasm should be checked by feeling the muscles, as an experienced patient may voluntarily assume the position. If no cramp appears after four minutes the test may safely be considered negative.

## The Hyperventilation Test

Various attempts have been made to utilize the response to hyperventilation as a diagnostic aid in latent tetany. Most authors mention the induction of tetany by hyperventilation, stating the time but not the rate. Lachmann (1941) in a detailed study of the subject considered hyperventilation a reliable means of revealing latent tetany, even more reliable than Trousseau's phenomenon, but his report did not mention controls. My first attempt (O'Donovan, 1943, 1945) to use hyperventilation consisted in getting the subject to breathe at the rate of 55 to 60 a minute for three minutes. If no tetanic manifestation appeared by then latent tetany was ruled out. In 72 normal adult controls it was observed that only 9 developed carpal cramp at or before three minutes.

This procedure has little practical value, as patients are likely to develop disturbing generalized signs and symptoms after hyperventilation for two or more minutes. Usually, it is also found positive only when the tourniquet test is already positive, therefore no further information is gained. In only 7 out of 64 instances of hypocalcaemia did it indicate latent tetany when the tourniquet test was negative. Details are given in the previous publications (O'Donovan, 1943, 1945).

## The Combined Test

Hyperventilation was found to be more practical in application if it was used only when the tourniquet test was negative and if begun immediately after release of the tourniquet. It can then very readily produce an isolated cramp in the ischaemic hand. The combination of the two procedures is referred to as the combined test, and the details are as follows.

The tourniquet is applied as described above for four minutes and if no definite carpal cramp appears it is removed and the subject is asked to breathe in and out deeply at 55-60 respirations a minute. He should be sitting upright, with the hands

placed loosely on the knees. The rate may be controlled by using rhythmic pressure on a shoulder with one hand while beating the time with the other. Respirations should flow evenly from expiration into inspiration without pause and should not be unduly forcible. The hyperventilation should be started within 15 seconds after releasing the tourniquet, and the procedure should therefore be explained to the patient before the tourniquet is released. Hyperventilation is stopped at 75 seconds or sooner if carpal cramp appears. In cases of latent tetany the hand previously under the tourniquet becomes spastic before 75 seconds, while there are few or no generalized symptoms of tetany. Rarely the opposite hand becomes cramped also, but not so intensively.

The standard of 75 seconds' hyperventilation is an approximation based upon 68 observations on adults and adolescents of all ages, including 25 female medical students. The same standard is used for both sexes, except that men are asked to hyperventilate more actively. Female medical students are always more sensitive subjects for the demonstration of latent tetany, partly because they tend to carry out the test with excessive enthusiasm and partly because young educated adults are more emotional than the average hospital patient. Hence some normal individuals of this type may reveal tetany even in 60 secs. This variation in the normal control is a disadvantage which is inherent in all tests for mild degrees of latent tetany, and the important characteristic of any test is that it should be positive in a high percentage of hypocalcaemic patients and in only a very small percentage of normal subjects. A positive test then indicates the necessity for a more detailed investigation of the possible causes of tetany.

Four out of the 68 controls developed cramp before or at 75 sec, whilst in 27 observations on 13 patients there were 23 positive reactions. In 58 observations based on Trousseau's sign, and the combined test where necessary, failure to diagnose latent tetany occurred in only three (95% positive) (see Table).

#### Evaluation of the Combined Test

The combined test is a useful procedure to demonstrate the phenomenon of carpal spasm to applied physiology classes. It shows that tetany is often a summation of factors which increase the sensitivity of the nervous system. In this case alkalosis and the hyperexcitability in the arm are augmenting one another. The test is of some practical value in checking the efficacy of treatment in chronic hypocalcaemic patients who have hypoparathyroidism or steatorrhea, as it obviates repeated blood analysis. In the individual patient on routine examination the error of variable degrees of hyperventilation is negligible, so that one can very readily detect a sudden drop in serum calcium. Finally, by improving bedside diagnosis the test should aid in the diagnosis of various diseases associated with latent tetany.

The combined test is an improvement on the simple hyperventilation test because it reduces the period of hyperventilation, eliminates the possibility of an unpleasant generalized tetany, and is more sensitive than either the tourniquet test or the hyperventilation test alone. It also reduces the frequency of the necessity to hyperventilate.

The disadvantages include its failure in cases of respiratory disease such as asthma and emphysema, recurrent laryngeal nerve paralysis after thyroidectomy, and abdominal tumours which prevent the proper movement of the diaphragm. The scope of the test in pregnancy has not yet been investigated. Lastly, in any serious physical or mental disability and in children under 10 years it would be difficult to obtain the necessary co-operation. These points are serious deficiencies in the routine use of the test. There were 4 patients in a total of 34 who were unable

to hyperventilate. In two of these Trousseau's sign was already positive, and therefore hyperventilation was not necessary.

#### Influence of Calciferol

In the initial phase of this investigation it was observed that when hypocalcaemic patients were taking calciferol (50,000 to 150,000 units daily) the tests for latent tetany were

■ Tests for Latent Tetany, Positive.  
○ Do., Negative

FIG 1

■ Tests for Latent Tetany Positive  
○ Do., Negative

FIG 2

frequently negative although the serum calcium was still subnormal. Fig 1 shows that this inhibitory action of calciferol on latent tetany cannot be entirely attributed to its effect on the serum calcium level. The data in Fig 1 were obtained by use of Trousseau's sign followed by hyperventilation when Trousseau's sign was negative. As already stated, in 58 observations on hypocalcaemic patients,

not taking calciferol, latent tetany was demonstrated in all but three instances. In 27 observations on patients who, notwithstanding calciferol treatment, still had hypocalcaemia the state of latent tetany was demonstrated in only five instances. Calciferol seems to have this effect irrespective of whether the patients have hypoparathyroidism or calcium deficiency. Study of individual patients clearly reveals the effect of calciferol (see Fig. 2).

### Discussion

What should be the clinician's criterion of dosage when treating chronic hypocalcaemia with calciferol? The drug appears to influence latent tetany both by raising the serum calcium and by some other independent effect. The doses required to inhibit the signs of latent tetany in the average case of hypoparathyroidism on ordinary diet is between 50,000 and 150,000 units daily. The dose necessary to keep the serum calcium within normal limits may be considerably larger. It would appear more reasonable to base the therapeutic dosage on a biological test than on a purely chemical estimation. The higher dosage necessary to keep the serum calcium around 10 mg per 100 ml may not only be unnecessary but may have a deleterious effect on the patient. It seems well established both in animals and in man that the toxic manifestations of vitamin D are not necessarily accompanied by hypercalcaemia (Reed, Struck, and Steck, 1939), while Eaton (1946) reported a hypoparathyroid patient taking calciferol who notwithstanding a normal serum calcium developed metastatic calcification.

The patients considered here, whose dosage and treatment were based on the signs of latent tetany, have so far shown no ill effect of low blood calcium such as lens opacities. The period of observation, however, is not long enough to permit conclusions.

It is difficult to explain the inhibitory action of calciferol on latent tetany that is not due to increased serum calcium. A relative increase in ionized calcium is at least a theoretical possibility. Unfortunately, complete data on serum protein are not available but in a small number of cases studied there was no appreciable change. Feeny, Sandilands, and Franklin (1947) found no change in the serum protein fractions, except a slight alteration of globulin fractions, in cases of lupus vulgaris receiving large doses of calciferol. Ingram, Anning, and Dawson (1948) recently reported that the high dosage of calciferol used in treatment of lupus vulgaris did not alter the ionized calcium fraction but significantly increased a diffusible calcium complex. It is unlikely that this alteration would have any bearing on the inhibition of latent tetany as described above.

### Summary

The clinical tests for detection of latent tetany in adults and adolescents were investigated, using hypocalcaemia as an index of latent tetany. Almost all the patients observed had chronic latent tetany. It was concluded that the well known tests are unreliable. The tourniquet test was negative in 34% of 89 observations on 32 patients and Chvostek's sign was negative in 73% of observations.

A new test combining the tourniquet test and hyperventilation is described. It is used when the tourniquet test is negative and is more reliable than either of the two procedures used separately. Of 58 observations on 32 patients 95% were positive. Two other patients whose tourniquet test was negative were physically unable to hyperventilate.

Calciferol has an inhibitory effect on the signs of latent tetany which is independent of the increase in serum calcium. In 22 of 27 observations on patients who had received a total of more than 500,000 units the signs of latent tetany were negatived although the serum calcium was still less than 9 mg

per 100 ml. Calciferol therefore inhibits latent tetany in two ways. The significance of this observation in the treatment of chronic latent tetany is discussed.

## PATHOGENIC STAPHYLOCOCCI

### DETECTION OF $\alpha$ -LYSIN PRODUCTION ON RABBIT- AND SHEEP-BLOOD-AGAR PLATES

BY

W. A. GILLESPIE, MD, DPH, MRCP

AND

P. M. SIMPSON, MB, ChB

(From the Bristol Royal Hospital (Infirmary Branch) and the Department of Pathology, University of Bristol)

The coagulase reaction is the simplest and perhaps the most important test for pathogenicity of the staphylococcus. However, the agreement between pathogenicity and this reaction, although close, is not absolute (Christie, North, and Parkin, 1946), and it is sometimes desirable to use confirmatory tests. This is especially the case when detecting carriers of pathogenic staphylococci. Christie and his co-workers (1946), having examined a very large number of strains, conclude that the production of  $\alpha$  lysin is the property most closely associated with pathogenicity. This conclusion is shared by Schwabacher *et al.* (1945).

Until recently it was commonly believed that the lysis of a blood-agar plate was an unreliable guide to pathogenicity. The relatively tedious detection of  $\alpha$  lysin in supernatants from broth cultures is still often recommended (Knott, 1947). However, several workers have used sheep blood-agar plates successfully for this purpose. The changes produced by  $\alpha$ - and  $\beta$ -lysins on this medium can usually be distinguished with ease (Naidu, 1934, Bryce and Rountree, 1936, Kojima and Kodama, 1939, Christie and North, 1941). Christie, North, and Parkin (1946), using spot inoculation of strains on sheep-blood-agar plates, observed that with nearly all haemolytic strains there was no difficulty in deciding whether they produced  $\alpha$  or  $\beta$ -lysin. However, with strains producing only a trace of lysis on blood agar it was difficult to decide whether this was due to  $\alpha$ -lysin or to something else. Williams and Harper (1947) describe a sheep-blood-plate method similar to that of Christie and his co-workers, except that a control plate containing incorporated  $\alpha$  antitoxin is included with each batch of tests, which are incubated in an atmosphere containing 30% CO<sub>2</sub>. They found that the method, although reliable, failed to detect about 2% of  $\alpha$ -toxicogenic strains (positive by broth method) and that  $\beta$ -lysin, when produced, could mask the  $\alpha$  lysin. They recommend that all apparently negative and all evidently  $\beta$ -toxicogenic strains should be tested in a tube before being classed as non- $\alpha$  toxicogenic.

The rabbit-blood-plate method of  $\alpha$  lysin detection described here is simple to perform and gives results which are easily interpreted. Other lysins do not interfere with the test.

## Method

Two per cent rabbit-blood-agar plates are used. The blood is obtained with reasonable aseptic precautions from an ear vein. The strain to be tested is streaked with a loop across the surface of the plate, previously dried in the incubator. Three or four strains can be tested on one  $3\frac{1}{2}$ -in (8.75-cm) plate. The number may be doubled by inoculating different strains on opposite halves of the plate. A strip of sterilized filter-paper about  $\frac{1}{2}$  in (1.25 cm) wide and containing dried  $\alpha$ -antitoxin is laid on the agar at right angles to the inoculation streaks. These papers are prepared by dipping dry-sterilized strips into  $\alpha$ -antitoxin (Burroughs Wellcome refined staphylococcus antitoxin, 1,250 units per ml). The papers are then dried in a Petri dish containing heated plaster-of-Paris and preserved, sealed in a similar dish, in the freezing chamber of an ordinary refrigerator. The method used is that described by Morley (1945) for penicillin-containing test papers. Sufficient papers for many tests may be prepared at one time. They retain their potency unimpaired for at least two months. We have not tested them after longer periods. Their content of dried serum renders the papers somewhat stiff, but

when applied closely to the agar they quickly absorb moisture and adhere to its surface.

Antitoxin papers may be prepared as required, without drying, by soaking in antitoxin and then blotting briefly. Excess fluid must be avoided, as it may allow the separate strains to run together along the strip when incubated.

The plates are incubated in an atmosphere containing approximately 30% CO<sub>2</sub>. After

Staphylococcus  $\alpha$  toxin production on rabbit blood-agar plate. One negative and two positive strains.

24 hours most of the positive strains give easily read results. If an apparently negative strain is present the plate is incubated similarly for a further 24 hours before the final reading. Strains which do not produce  $\alpha$  toxin give either no lysis or, more often, a sharply bordered zone of lysis the edge of which is parallel to the growth and which extends right up to the edge of the filter paper. On the other hand, an  $\alpha$ -toxigenic strain shows a wide zone of lysis with hazy margins. Near the filter paper this zone tapers in the form of a spear-head pointing towards the paper (see illustration). This spear-head zone of narrowing, diagnostic of  $\alpha$ -toxigenic strains, is sharply defined by remarkably straight borders corresponding to lines of toxin-antitoxin neutralization. In addition, it is often possible to see straight white lines extending outwards at an angle from the filter-paper. These lines correspond closely with the borders of the haemolysed zone, and are apparently formed by toxin-antitoxin precipitation in zones where optimal proportions exist (Elek, 1948). The presence of other lysins in addition to  $\alpha$ -toxin makes no difference to the clarity of the result.

Identical appearances are obtained by spreading antitoxin (4 drops) over half a previously dried plate. The plate is dried again, and strains are then streaked across it at right angles to the dividing line between treated and untreated agar. The necessity for a second drying of the plate renders this technique less convenient than the filter-paper method.

## Results

Using this method we examined 201 unselected pure strains of staphylococcus freshly isolated from routine hospital specimens over a period of eight months. The strains were all tested at the same time for  $\alpha$ -toxin production in broth (Gillespie, Devenish, and Cowan, 1939) and for coagulase production (Gillespie, 1943). The results obtained are shown in the Table.

Table showing Coagulase Reactions and  $\alpha$ -Toxin Production by 201 Strains of Staphylococcus

Rabbit Blood-Plate Test	$\alpha$ Toxin in Broth		Coagulase	
	Positive	Negative	Positive	Negative
162 $\alpha$ toxin positive strains	162	Nil	162	Nil
39 $\alpha$ toxin negative strains	1	38	6	33

On purely clinical grounds it was impossible to be certain of the pathogenicity of the majority of the staphylococci examined. However, 37 strains were certainly pathogenic for man (isolated from pus from previously unopened, non-contaminated abscesses, films of which showed clusters of Gram-positive cocci only and which yielded pure cultures of staphylococcus). Of these 37 certainly pathogenic strains 36 were positive by both plate and broth test and 37 were coagulase-positive. Evidently the correlation between pathogenicity and  $\alpha$ -toxin production on plates is close.

Plate methods of detecting  $\alpha$ -toxin production are much more simple to perform than the broth method. In addition, the interpretation of the results of the latter is sometimes rendered difficult by haemolysis occurring rapidly in the control tube (due to lysins other than  $\alpha$ -toxin).

**Sheep-Blood-Agar Plates**—We have used the filter-paper-strip method on sheep-blood plates in parallel with rabbit-blood plates in testing 33 strains (20  $\alpha$ -toxin-positive and 13 negative). Identical results were obtained in this small series. The specific spear-head zone of lysis is as clear as with rabbit blood, but presumably there is a danger that small amounts of  $\alpha$ -lysin may be obscured by  $\beta$ -lysin if sheep blood is used (Williams and Harper, 1947).

## Summary

A plate method of detecting staphylococcus  $\alpha$ -toxin production is described. Filter-paper strips containing  $\alpha$ -antitoxin are used on 2% rabbit-blood-agar plates incubated in an atmosphere containing 30% CO<sub>2</sub>. The interaction of the toxin and antitoxin diffusing into the agar at right angles to one another causes a sharp tapering of the wide zone of lysis surrounding  $\alpha$ -toxigenic strains. This appearance is specific for such strains.

The test is easy to perform and to interpret, and the results have shown a close correlation with tube  $\alpha$ -toxin tests, coagulase production, and the clinical pathogenicity of the strains examined.

## A CASE OF DICOUMAROL POISONING

BY

J. A. WAKES MILLER, MB, MRCP

Physician Hospital of St Cross Rugby and Nuneaton General Hospital

AND

J. K. DRUCQUER, MB, ChB

Clinical Assistant Medical Unit Hospital of St Cross Rugby

The following case emphasizes the grave danger of the use of the anticoagulant dicoumarol without adequate laboratory control. It also stresses the importance of the use of fresh blood and not stored blood in the therapeutic control of haemorrhage from dicoumarol overdosage. Vitamin K and stored blood are without effect. There is a definite latent period before therapeutic measures can take effect, and various mechanical factors may have to be dealt with. The reaction to treatment, when it occurs, is dramatic, and no case can be considered hopeless. In this instance, despite the severe and generalized nature of the haemorrhages, complete recovery occurred.

## Case Report

The patient, a man aged 57, was admitted to hospital on account of severe haematuria on Oct 4, 1947. He had read in the daily papers that dicoumarol had been used for coronary thrombosis but it was not known that the cause of the haematuria was dicoumarol until a detailed history was taken and by this time various other severe haemorrhagic symptoms were present. It was revealed that on his own initiative he had taken 100 mg daily for nine or ten days. There was a latent period of seven days before signs and symptoms appeared. This latent period has been previously pointed out by Crawford and Nassim (1944). The first symptom was abdominal pain which preceded sudden gross haematuria by 24 hours.

Within 24 hours of being admitted to hospital the patient's general condition deteriorated rapidly. Multiple petechial haemorrhages occurred in the skin and subcutaneous tissues then melæna and a massive sublingual haematoma developed which increased in size hourly. The initial B.P. was 160/115. The tongue became the size of a tangerine orange and immediately threatened to obstruct his airway. Despite the immediate transfusion of blood the swelling of the tongue increased and a tracheotomy was performed while transfusions were continued. A considerable submandibular haematoma developed and the patient was in *extremis*. His B.P. was 90/74 on Oct 7. The anaemia was relieved but haemorrhages continued. A pint (570 ml) of stored blood was given with vitamin K injections intramuscularly; the response was not satisfactory, and haemoptyses occurred. X-ray examination with a portable apparatus revealed multiple shadows in the lung fields. Further transfusion of 1 pint of fresh blood was given on Oct 8, but his condition remained precarious. A further 3 pints (17 litres) of blood was obtained from the relatives and this was given by slow drip over the next 48 hours. His condition gradually improved and the haematuria and petechial haemorrhages decreased. Whole blood transfusion had a dramatic effect on the prothrombin times. These were Oct 7 47% normal, Oct 8 48% normal, Oct 9 50% normal, Oct 17, 57% normal.

Examination of the blood on Oct 5 showed haemoglobin 82%, red cells 3 600 000, white cells 12 200, reticulocytes, 3%, platelets 108 000. On Oct 10 the haemoglobin was 50%. On the 14th the white cells numbered 8 000, reticulocytes 7%, platelets 240 000. On the 17th the haemoglobin was 97%, red cells 4 800 000, white cells, 8 600, reticulocytes 5%, platelets 288 000.

## Discussion

Dicoumarol must be considered in the differential diagnosis of all cases of haematuria in which the drug has been taken. This is discussed by Rosenbloom and Crane (1946). It would appear that haematuria is one of the earliest signs

of dicoumarol intoxication and an indication for correct therapy, as more severe symptoms may quickly supervene in a matter of hours. In our case venesection before transfusion was not performed, as was practised by Shlevin and Lederer (1944), although there was a definite danger of left-sided heart failure from a recent coronary thrombosis. Jaundice developed 130 days after the initial transfusion. This was taken to be of the homologous serum type rather than due to any direct toxic action of the dicoumarol on the liver. Jaundice as a manifestation of dicoumarol poisoning has not yet been reported. The present case, we think, illustrates the importance of including dicoumarol in the list of dangerous drugs.

Grateful thanks are due to Sister B. Coys for correlation of clinical details, to Mr F. J. C. Matthews, assistant surgeon, for performing the tracheotomy, to Dr R. C. Hill, pathologist, and to Mr F. J. Howe, Hospital of St Cross.

## Medical Memoranda

## Auricular Fibrillation after Trichlorethylene Anaesthesia

The following case is unusual enough to merit publication. It is of interest in that although the occurrence of vagal inhibition (Haworth and Duff, 1943), sinus bradycardia, and auricular and ventricular extrasystoles (Hewer, 1942, 1943; Barnes and Ives, 1944) has been noted during anaesthesia with trichlorethylene, there is only one record in the current literature (Lloyd Williams and Hewspear, 1942) describing the onset of auricular fibrillation in association with this form of anaesthesia, although by now innumerable administrations have been given in this country alone.

## CASE HISTORY

A healthy woman aged 50 was admitted to hospital for the repair of a large cystocele and rectocele. She had always been in excellent health, and at the pre-operative examination she appeared to be very fit, with no clinical evidence of cardiovascular disease. The blood pressure was 140/90. She was, however, unduly nervous and apprehensive.

Pre-operative medication consisted of 1/6 gr. (11 mg.) of morphine and 1/150 gr. (0.43 mg.) of hyoscine. Anaesthesia was induced with 0.5 g. of sodium thiopentone, and this was followed by nitrous oxide, oxygen, and trichlorethylene, using a "semi-closed" technique with the standard Boyle machine. Induction and maintenance were smooth and uneventful. Anoxia was not permitted at any time, and there were none of the usual signs to indicate overdosage of the drug—which was not surprising, as an absolute minimum was used. No irregularities of the pulse were noted during operation, which lasted 55 minutes. At the end of the operation the patient's general condition was good, but the pulse rate was rather slow (65).

Fifteen minutes later we were called to the ward, she was almost conscious, but sweating profusely and rather pale, with a pulse rate of 40. In the absence of other findings it was considered that this might be a vagal effect and 1/100 gr. (0.65 mg.) of atropine sulphate was given intravenously. Within two minutes the pulse rate had returned to 65–70 and remained so, although from time to time multiple extrasystoles could be detected by palpation and auscultation. Four hours later we were again called to see her and found that she was dyspnoeic and slightly cyanosed, but apart from the dyspnoea she felt quite comfortable. On examination auricular fibrillation was present with a ventricular rate of approximately 165. There were no other abnormal clinical signs. A course of intensive "digoxin" therapy was instituted. The following morning auricular fibrillation was still present but the ventricular rate was down to 100 and the cyanosis and dyspnoea had disappeared. By evening the fibrillation had ceased and the cardiac rhythm was completely regular, the pulse rate being 75. Digoxin was discontinued and the cardiac rhythm remained normal. Further convalescence was uneventful. Unfortunately it was impossible to have an electrocardiogram taken during the period of fibrillation, but clinically the diagnosis was never in

doubt Electrocardiograms taken subsequently showed no abnormality in rhythm or evidence of myocardial disease. There was no evidence of thyrotoxicosis and the blood Wassermann reaction was negative. One month after operation the patient was symptomless and was carrying out her normal household duties.

## COMMENT

The work of Meek, Hathaway, and Orth (1937) and Meek (1940) has provided useful information with regard to the effects of anaesthetic agents on cardiac automaticity. It seems likely that arrhythmias arising below the sino-auricular node are due to vagal stimulation, which causes depression of the sino-auricular node, bradycardia, and the appearance of auricular and ventricular extrasystoles (escape phenomena). Because of this depression of the sino-auricular node the ventricular muscle is rendered more sensitive to stimulation, particularly by adrenaline, and ventricular fibrillation may occur. This is presumably the mechanism of ventricular fibrillation occasionally seen during chloroform anaesthesia. Trichlorethylene is of course very similar to chloroform in chemical composition, and clinical reports bear out this similarity of action, although it is much less toxic and potent. Waters, Orth, and Gillespie (1943), basing their opinion on only a few cases, decided that the drug might have undesirable effects on cardiac automaticity, but up to the present time clinical experience has not really justified this view. In their electrocardiographic investigation of 40 patients undergoing operations under trichlorethylene anaesthesia Barnes and Ives (1944) demonstrated various simple arrhythmias such as sinus bradycardia and auricular and ventricular extrasystoles, but found no evidence of auricular or ventricular fibrillation.

In our case the sequence of events—vagal stimulation with bradycardia, extrasystoles (presumably auricular), and auricular fibrillation—was well demonstrated. Theoretically there would seem to be no reason why auricular fibrillation and not ventricular fibrillation should not follow on multiple auricular extrasystoles in the absence of suitable ventricular stimulation—e.g., excess adrenaline. This case is of further interest in that the cardiac arrhythmias occurred in the immediate post-operative period, when presumably most of the trichlorethylene had been excreted. Adrenaline was not used during operation nor was the patient intubated—factors present in the other recorded case. In view of the patient's state of health both before and after operation it is difficult to dissociate the trichlorethylene anaesthesia and the onset of fibrillation.

It should be noted that the trichlorethylene used in this case was from a newly opened bottle which when subsequently examined conformed to the usual tests of purity. Several patients have since been anaesthetized with trichlorethylene from the same bottle without untoward effect.

## An Unusual Trophic Ulcer

Numerous papers have been written on lesions of the lumbar intervertebral disks and their relation to sciatic pain since the pathology was described by Love in 1939. In addition to sciatic pain other conditions have been ascribed to disk lesions. Massive extrusions of the lumbar disks are known to produce cauda equina lesions with severe sphincter disturbances (ver Bruggen 1945). Pennybacker (personal communication) has seen trophic ulcers complicating cauda equina lesions due to prolapse of the lumbar disks. Burns and Young (1945) attribute the majority of cases of chronic backache to disk lesions.

Search of the extensive literature has failed to reveal any reference to a trophic ulcer of the foot being produced by an old lesion of a lumbar intervertebral disk and it is thought that the following case is of sufficient interest and importance to merit publication.

The usual causes of trophic ulcers given in neurological text books are tabes dorsalis, diabetes, spina bifida occulta, leprosy, and syringomyelia (rarely). As trophic ulcers are not uncommon

it is possible that not a few are due to old disk lesions which have been missed because the more usual causes are not common maladies, with the single exception of diabetes. Furthermore, Schmorl (1927) finds prolapse of an intervertebral disk present in 38% of necropsies. Leigh (1947) points out that sensory regeneration may not occur, as compression of the nerve root in disk lesions involves the sensory fibres most of all.

## CASE REPORT

A truck-driver aged 29 was referred from the surgical to the medical out-patient department on account of an absent right ankle-jerk. In March, 1947, he was seen in the surgical out-patient department on account of an excavated and discharging ulcer on the plantar surface of his right heel. It was painless and had been present for about 10 weeks. He denied injuring his heel. Excision was advised. A week later he was admitted to a surgical ward, and two days later the ulcer was excised under a general anaesthetic. The wound was packed with vaselined gauze. He was discharged after a week, a radiograph of the foot taken at this time showed that there was no bony lesion or radio opaque foreign body in the heel. A week later the ulcer was healing satisfactorily. A section of the ulcer showed "capillary thromboses and haemorrhages in dermal papillae in a portion of horny skin from the heel."

He was seen again on Aug 11, 1947, when he said that the ulcer had broken down some eight weeks previously, but it was still painless. Further inquiry into his history elicited the following information. In March, 1944, he had had pain in the right side of the back, buttock, and down the back of the thigh and leg to the lateral border of the foot and of the heel, the pain had lasted 10 weeks and he had been away from work for six weeks. When the pain had subsided it had been replaced by numbness of the outer side of the right foot and heel. There was no history of trauma. At no time had there been any disturbance of micturition.

On examination he was seen to be a healthy-looking man. The only abnormal neurological signs in the legs were an absent right ankle jerk and marked impairment of pain and touch sensibility over the lateral border of the foot, both dorsal and plantar surfaces of the heel, and of the posterior aspect of the thigh. Flexion of the extended leg at the hip was painless (Lestegue's sign negative). The ulcer measured 1 by 1 cm and was 0.5 cm deep, it had a granulated base and undermined edges. The arteries of the right foot were easily palpable. There was some loss of normal lumbar lordosis and flattening between the fifth lumbar spine and the first piece of the sacrum. There was no tenderness anywhere, and movements were full. No other abnormal physical signs were found in the central nervous system. Wassermann and Kahn reactions were negative. Radiographs showed no abnormality of the lumbo-sacral region.

It was not considered justifiable to submit this patient to laminectomy, his disability was slight, he was at work, and the long history suggested damage to the posterior nerve root which was probably permanent. Accordingly local treatment to the ulcer was intensified.

## DISCUSSION

This case well illustrates the following points: (1) The typical sciatic pain in 1944 was replaced by numbness over the lateral side of the foot and heel—a point which is often missed in the history, as the patient pays little attention to numbness compared with the severe pain, the numbness tends to persist. The length of the history and the absence of progression of symptoms almost certainly exclude a very slowly growing tumour compressing the first sacral nerve root. (2) The abnormal neurological physical signs and flattening of the lower lumbar spine suggest a prolapse of the disk between the fifth lumbar and first sacral vertebrae. These signs tend to persist. (3) The ulcer was no doubt due to the impairment of pain sensibility, which corresponds to the sensory division of the first sacral nerve root, it was this root which was compressed by the extruded disk. (4) The relation of the sciatic pain three years previously was not correlated with the ulcer of the foot until the question of the absent ankle jerk presented itself for elucidation.

My thanks are due to Dr S A Probert, honorary physician, and Mr Ronald Reid, honorary surgeon, Essex County Hospital, Colchester, for their interest and encouragement in the preparation of this report.

## Reviews

### JUVENILE DELINQUENCY

*Juvenile Delinquency in an English Middletown* By Hermann Mannheim International Library of Sociology and Social Reconstruction (Pp 131 12s 6d) London Kegan Paul Trench Trubner and Co 1948

The latest addition to the International Library of Sociology and Social Reconstruction is a sociological study of juvenile delinquency on regional lines. The author believes that oecological studies of delinquency afford a promising line of approach, supplementing statistical mass inquiries and prolonged studies of a few individual cases. He describes the nature, causes, and treatment of delinquency in the Borough of Cambridge and in his task has received valuable information from authorities and officials.

Dr Mannheim found that during the five years 1941 to 1945 the average figure for indictable offences committed by juveniles in Cambridge was exactly twice the figure given by Dr E C Rhodes for the borough in 1934 to 1936. But in comparison with other localities the increase was not considered to be particularly high. Among many interesting data the fact that some of the new housing estates showed a considerably higher incidence of juvenile delinquency than the town as a whole has some general interest. The author considers that rehousing in itself is no panacea for social evils unless accompanied by social services such as youth centres and other measures which deal with some of the needs of a youthful community. In the absence of statistical data Dr Mannheim was unable to accept the suggestion that the cause of the delinquency was attributable to a greater number of children in the families than in other wards.

While stressing the need for further research into juvenile delinquency by persons not engaged in the treatment of offenders, Dr Mannheim believes that such studies should be supplemented by those of probation officers, institutions for juvenile delinquents, and child guidance clinics. The data collected are instructive and the recommendations on the administration of juvenile courts are provocative. The book is written with the author's usual lucidity and is a welcome addition to the increasing literature on the subject.

W NORWOOD EAST

### ORAL IMMUNIZATION

*Oral Vaccines and Immunization by Other Unusual Routes* By David Thomson OBE, MB ChB DPH and Robert Thomson, MB ChB. Assisted by James Todd Morrison, MD, DPH (Pp 329, £2 2s) Edinburgh E and S Livingstone 1948

This monograph is in the main a review of the literature, over 1,000 papers being quoted, and in part an account of the authors' own experiences. They begin by declaring their belief that immunity can be obtained by vaccines administered orally, or by inunction spraying into the nose or trachea, or instillation into the conjunctival sac. They grant that the results are less certain and that much more frequent repetition is necessary than when the parenteral route is used but unpleasant reactions are obviated and what may be called needle resistance is circumvented. They review very fully the literature on oral vaccination against enteric fever and dysentery, the most logical and best supported example of this method. They also give a long account of oral BCG, although this form of vaccination differs radically in principle from the others considered in that the vaccine is a living one even so it is noteworthy that the oral administration of BCG has now been superseded. From these and other more or less reasonable subjects the authors descend to discussing with apparent seriousness such unscientific practices as treating diphtheria with oral antitoxin, ulcerative colitis with an oral *Bergens coccus* vaccine, and pyorrhoea with a vaccine-containing toothpaste. If the authors write from too credulous a standpoint for us always to respect their conclusions we must nevertheless be grateful to them for a guide to the literature of an obscure and interesting subject.

L P GARROD

### PEPTIC ULCERATION

*Ulcer of the Stomach, Duodenum and Jejunum* By Ralph C Brown M.D. Edited by Henry A Christian, M.D. Sc.D. F.A.C.P. F.R.C.P.(Can) (Reprinted from the Oxford Loose Leaf Medicine with the same page numbers as in that work) Oxford Medical Publications (Pp 108, illustrated 12s 6d) New York and London Oxford University Press (Grosvenor Chumley)

This small book is a reprint of the chapters on peptic ulceration in the *Oxford Loose Leaf Medicine*. It is a concise but complete account of the modern view of the subject. The author was a pupil of Sippy's, and for many years has himself been in charge of the clinic at the Presbyterian Hospital in Chicago where Sippy worked. The book therefore not only has an authoritative air but is at all times very practical.

To cover the whole subject in a little more than 100 pages considerable condensation has been necessary, and in order to produce a balanced narrative the author draws fully on his own experience. Nevertheless some gaps must occur and the author gives an account of some procedures not in general use but which no doubt are most successful in his hands. Thus he makes the clinical differentiation between peptic ulcer and gall bladder disease and functional dyspepsia sound very simple. Similarly, in the treatment of severe haematemesis when it is thought that bleeding is continuing he advocates gastric lavage with ice cold water followed by 15 ml of adrenaline by mouth. There is a good bibliography and the book is well illustrated by tracings from radiographs.

CHRISTOPHER HARDWICK

### STATE MEDICINE IN ENGLAND

*The History of State Medicine in England* Being the FitzPatrick Lectures of the Royal College of Physicians of London for the years 1946 and 1947. By Sir Arthur S MacNalty, KCB, MA MD, FRCP, FRCS (Pp 82 12s 6d) London Royal Institute of Public Health and Hygiene

Most of this book is occupied by the FitzPatrick Lectures given at the Royal College of Physicians in 1946 and 1947 which deal with the period from the accession of Victoria to the establishment of the Ministry of Health in 1919. But the author has greatly improved the book by including the lecture on the "Evolution of Preventive Medicine in England" given at the Royal Society of Medicine in 1946. Thus he has concisely covered the whole ground. His account is no dry summary for it is lit up by many attractive biographies of the persons chiefly concerned, particularly those who inspired progress in the late nineteenth and in the present century. While paying his due meed of praise to the early pioneers, Sir Arthur claims that Southwood Smith, Arnott, and Kay were the medical architects and Edwin Chadwick the actual builder of the edifice. His sidelights on the personalities of the men with whom he was personally familiar, such as Horsley Klein Thorne Thorne, Downes, Monckton Copeman and Newsholme, are illuminating. His generous reference to James Kerr whose pioneer work in school welfare is apt to be forgotten is well deserved. The book is copiously documented written in an easy attractive style and is a useful epitome of how a system grew up in which the author has taken an active part. The publishers deserve commendation for the attractive appearance of the book.

ALFRED COX

### A PSYCHIATRIC SYNTHESIS

*Psychiatry A Short Treatise* By William A O'Connor L.M.S.S.A. D.P.M. (Pp 380 35s) Bristol John Wright and Sons 1948

This is a short textbook of psychiatry for students of psychiatry, and is not suitable for use as a reference book or as a text for unqualified students. It is interesting for the attempt the author makes to combine psycho-analytic doctrine with a classical nosology. The two do not, unfortunately, combine at all well. The author himself feels that it is 'a far cry from the basement membrane of the testis to the meta-psychological theorizings of the psychoanalysts'. The book is full of such asides. Discussing the sometimes pleasurable tone of very mild anxiety feelings he remarks "Is it then true to say that in the midst of a life giving process we feel the threat of dissolution? Or is it nearer the truth to suppose that in the midst of satisfying a biological need we fear lest the ultimate orgasm fail us?"

There is an unfortunate emphasis on body-mind dualism. The somatic aspects of schizophrenia are to be seen only in its 'strange and inexplicable physical symptoms. Behaviour becomes understandable when described by far-fetched analogies—e.g., he describes psychoses as anaphylactic phenomena sensitization having been produced by repeated psychic shocks. Preclinically, physical disease is an unconscious process. One may expect to find psychic symptoms of the presence of schizophrenia in early childhood. The author's point of view is a highly individual one. Nevertheless there is much of interest. He describes the historical development of psychiatric concepts at greater length than is usual, and though his account will probably not help the student much it will interest the psychiatrist. His discussion of the more important recent advances, including physiological and genetical studies as well as psycho-analytical, is for the most part adequate. Even though it seems quite unsuccessful to the reviewer, a synthesis has been attempted, and the writing is both lucid and fresh.

ELIOT SLATER

### DENTAL DISEASE AND PATHOLOGY

*Oral and Dental Diseases* By Hubert H. Stones, M.D., M.D.S., F.D.S.R.C.S. (Eng.) (Pp. 896, 926 illustrations, 82 in colour £4 10s.) Edinburgh: E and S Livingstone, Ltd.

*Surgical Pathology of the Mouth* By E. Wilfred Fish, C.B.E., M.D., Ch.B., L.D.S. (Munch.), D.D.Sc. (Melb.), D.Sc. (Lond.), F.D.S.R.C.S. (Eng.) (Pp. 463, 236 figures, 50s.) London: Sir Isaac Pitman & Sons Ltd.

It is a coincidence that two such excellent books should have been produced at the same time, when a want for them has been felt for many years. Both books are very well produced and illustrated, and while Professor Stones covers a wider field Dr. Fish has selected certain aspects of oral and dental pathology which he discusses in detail, the former is more impersonal and the latter more personal. The information in both books is up to date, and the references at the end of each chapter in *Oral and Dental Diseases* make it easy for the reader to find more on any subject. Dr. Fish describes the pathology underlying many surgical procedures, and the book is in fact largely founded on experimental work.

The books are complementary to each other. Professor Stones should be very useful to both student and practitioner for information and reference. Dr. Fish's is more about the pathology of certain clinical conditions and should equally certainly be read by student and practitioner.

ALEXANDER MACGREGOR

We receive again—perhaps for the last time, but we hope not—*The Hospitals Year Book 1947* edited by J. P. Wetenhall (The British Hospitals Association 21s.). It is a useful directory listing all the hospitals in Great Britain and Ireland local authority as well as voluntary. A new feature this year is a list of hospitals providing rehabilitation services. There are between 300 and 400, though in some cases the organization is still meagre. The editor gives some forecast of hospitals in the new National Health Service, but he points out that the Act, with a frequency unparalleled in former legislation, "relegates every aspect of administration to be dealt with in future regulations and orders. Yet it is the administration, not the Act itself which will determine whether the new Service is good, bad, or indifferent. He points out also the dangers of standardization—a word with a double meaning, connoting perhaps the creation of standards of quality design, and manufacture, or perhaps only a dead level of mediocrity. It might be thought that in a nationally organized hospital service economy and enhanced efficiency are to be expected owing to central buying of supplies and uniformity of equipment, but Mr. Wetenhall shows that these methods while they have their value, will not necessarily do all that is expected of them especially if they are indiscriminately or excessively used. Discussing the medical staff he urges the importance of a medical committee at each hospital in close contact with the house or management committee. The internal administration of the hospital must be such as to ensure professional freedom in the treatment of patients and the prosecution of research. It is hinted that this may be the last issue of the year-book, for it is published under the auspices and at the expense of the British Hospitals Association which can no longer exercise a representative function on behalf of voluntary hospitals once such hospitals have lost their voluntary status. But the new era in hospital administration will be at a disadvantage if it is deprived of what Mr. Bevan himself in a foreword calls "an institution in the hospital world," and it is to be hoped that in some form or other it will be continued.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*The Surgery of the Stomach and Duodenum* By T. H. Somervell, M.A., M.B., B.Ch., F.R.C.S. (Pp. 546, 45s.) London: Edward Arnold, 1948.

Includes detailed descriptions, with illustrations by the author, of operative methods.

*Biology of Disease* By Eli Moschcowitz, M.D. (Pp. 221, \$4.50.) New York: Grune and Stratton, 1948.

Essays on the aetiology and pathology of a number of diseases.

*The Pathological Physiology of Uremia in Chronic Bright's Disease* By S. E. Bradley, M.D. (Pp. 69, 10s. 6d.) Oxford: Blackwell Scientific Publications, 1948.

The author relates the functional disorders of various organs to the clinical manifestations of uraemia.

*Medical Hypnosis* By L. R. Wolberg, M.D. Vol. 1 (Pp. 449, \$5.50.) Vol. 2 (Pp. 513, \$6.50.) New York: Grune and Stratton, 1948.

The use of hypnosis in psychotherapy.

*Co-operation, Tolerance, and Prejudice* By S. Lowy, M.D. (Pp. 318, 21s.) London: Routledge and Kegan Paul, 1948.

The sociology and psychology of intolerance and prejudice.

*Malleus Maleficarum* Translated by the Rev. Montague Summers. (Pp. 278, 15s.) London: Pushkin, 1948.

The first translation into English of this famous work on the extermination of witches.

*Radiotherapy and Cancer* By A. G. C. Taylor, M.R.C.S., L.R.C.P., D.R., F.F.R., and others. (Pp. 81, 7s. 6d.) London: H. K. Lewis, 1948.

A summarized account based on the authors' experience.

*Essentials of Pathology* By L. W. Smith, M.D., F.C.A.P., and E. S. Gault, M.D., F.C.A.P. 3rd ed. (Pp. 764, \$12.00.) Philadelphia: Blakiston Company, 1948.

A textbook for medical students.

*Kleine Chirurgie* By Hans Kurtzahn, revised by W. Heyn. 12th ed. (Pp. 496, M 17.50.) Berlin: Urban and Schwarzenberg, 1948.

A short textbook of surgery.

*Wetter und Krankheiten* By H. Berg. (Pp. 140, M 6.50.) Bonn: H. Bouvier, 1948.

An account of the relation between climate and disease.

*Die Immunitätsforschung Die Antigene* By R. Doerr. Vol. 3. (Pp. 375, No price.) Vienna: Springer, 1948.

A monograph on research into antigens.

*The Diabetic A B C* By R. D. Lawrence, M.A., M.D., F.R.C.P. 10th ed. (Pp. 80, 4s.) London: H. K. Lewis, 1948.

Instructions for the diabetic patient.

*Le Foie Vasculaire* By M. Favre. (Pp. 98, 220 francs.) Paris: Masson, 1948.

A monograph on hepatic cirrhosis.

*Traité de Médecine* Edited by A. Lemierre, and others. Vol. 7. (Pp. 1063, 2,300 francs.) Paris: Masson, 1948.

This volume is on the alimentary system.

*Modern Trends in Psychological Medicine 1948* Edited by N. G. Harris, M.D., F.R.C.P., D.P.M. (Pp. 450, 50s.) London: Butterworth, 1948.

Contributions by various authorities.

*Conception Physique de la Vie* By D. Clewaert. 2nd ed. (Pp. 234, No price.) Paris: Librairie Maloine, 1948.

The author describes his theory of density and tensions in living organisms.

## SPONTANEOUS PNEUMOTHORAX

Since Kjaergaard<sup>1</sup> published his careful studies non-tuberculous spontaneous pneumothorax has been easy to recognize clinically, and it is not usually difficult to distinguish between it and spontaneous pneumothorax occurring as a result of pulmonary tuberculosis. Simple non-tuberculous pneumothorax is characterized by absence of previous symptoms of disease, afebrile course, normal sedimentation rate, absence of pleural exudate, uneventful re-expansion of the lung in most cases, and failure to find radiological evidence of pulmonary disease in the re-expanded lung. Cases are relatively rare in which doubt remains whether the condition is tuberculous or non-tuberculous after consideration of all these factors, and the treatment of the majority of cases of simple spontaneous pneumothorax presents no difficulty. Some patients are liable to recurrent attacks, and the occasional case in which the lung fails to re-expand and the pneumothorax becomes chronic presents a special, though rare, problem.

The mechanism responsible for simple spontaneous pneumothorax, especially the chronic and recurrent types, has not been thoroughly investigated, though isolated cases showing cystic and bullous emphysematous changes of various sorts have been reported and valvular mechanisms have been demonstrated histologically.<sup>2,3</sup> The publication by R. C. Brock<sup>4</sup> of his observations on 71 cases of recurrent and chronic spontaneous pneumothorax is therefore most informative and welcome. He defines chronic pneumothorax as one which has failed to re-expand after three months; there were 45 of these cases, 17 of which became chronic after recurrent attacks. The average duration was 15 months and the longest 9½ years. The recurrent group consisted of 25 cases (excluding the 17 which became chronic). Fifteen of the recurrent cases had alternating bilateral attacks, and in 8 both lungs became collapsed simultaneously. The teaching of Kjaergaard and others about non-tuberculous spontaneous pneumothorax does not yet seem to be widely enough known, since Brock remarks that many of his patients had wasted time undergoing sanatorium treatment. The ages of his patients ranged from 1½ years to 64 years. The age distribution within this range differed from that in the series of 358 cases of simple pneumothorax collected by Perry,<sup>5</sup> since in his series the condition developed most frequently in the third decade, whereas in Brock's series of recurrent and chronic cases the greatest incidence was spread over the third, fourth, and fifth decades. This difference was probably due to the greater number of cases with gross emphysematous changes in Brock's series.

In only one of Brock's cases was tuberculosis found to be the cause. In one case the pneumothorax had produced

no symptoms and was discovered accidentally, and in others a small pneumothorax was found on the opposite side to that which was being investigated. In the severe cases of chronic pneumothorax there was often great loss of weight, which was regained after the lung had been induced to re-expand. Ordinary radiographic examination may show nothing more than the pneumothorax, though emphysema may be seen in the opposite lung. It may be difficult to distinguish between pneumothorax and a giant cyst or bulla, but it is of practical importance, since needling a bulla in the mistaken belief that it is a pneumothorax may result in a tension pneumothorax if the pleura is free, and this can produce severe symptoms or even be fatal. Tomography or bronchography may help to differentiate the two conditions. If it is thought advisable to needle a patient before it is known for certain whether the condition is a bulla under tension or a pneumothorax, preparations should be made for the treatment of tension pneumothorax if necessary, or even for the performance of thoracotomy. Intrapleural pressure readings are valuable in demonstrating conclusively the presence of a fistula, which is shown by a rapid return of the pressure to the previous reading after withdrawal of air. Thoracoscopy is the most valuable examination and should never be omitted.

Brock was able to find the probable cause of the condition in all except six of his seventy-one cases; in these six no cause was discovered even after the most exhaustive investigation. Emphysema was present in 25 cases, in 13 of which it was classified as bullous; 8 patients also had asthma and bronchitis. In 11 cases there were large solitary bullae or cysts, in three diffuse polycystic disease, in 15 small bullae, mostly apical, and in six an apical scar. The actual leak or tear was seen through the thoracoscope in four cases. An interesting observation is the appearance of areas resembling "cuckoo spit". In three of the patients in whom it was found emphysema was also present, but in the fourth there was no other evidence of abnormality in the lungs. The area is made up of a number of scattered foci on the pleura consisting of a few tiny air bubbles each less than a millimetre in diameter. When the patient was instructed to make expiratory efforts with the nose held these clusters of air bubbles became larger and the number of bubbles increased. Brock suggests that these foci can probably disappear and reappear in different places, and this would explain why no abnormality has been found at post-mortem examination in the lungs of some patients dying with spontaneous pneumothorax. He considers that in these cases there is a defect of quality, presumably congenital but possibly acquired, which makes the pleura liable to leak or rupture easily. In one case he observed rupture of the pleura during a thoracoscopy when a swab holder slipped and fell gently on to the lung. Brock's conclusion is that there are several conditions which may cause chronic and recurrent spontaneous pneumothorax. It may arise in the pleura from tearing at the site of an adhesion or from defective quality of the pleura itself; it may be subpleural from bullae, either in connexion with old scars or with

<sup>1</sup> *Acta med scand Suppl* 1932, 43<sup>2</sup> Hayashi J. *Frankfurt Z Path* 1915 16 1<sup>3</sup> Fischer B. *Z klin Med* 1922 95 1<sup>4</sup> *Thorax* 1948 3 88<sup>5</sup> *Quart J Med* 1939 8 1<sup>6</sup> *J thorac Surg* 1935 4 251

emphysema, and possibly from congenital maldevelopment of alveoli, it may lie in generalized changes in the alveoli in the form of emphysema, or it may be in the bronchioles or bronchi as in congenital or acquired cystic conditions.

Treatment depends on the cause. If the condition is due to large localized cysts or bullae (such cases are in the minority) the correct treatment is excision, either by lobectomy or local resection. Brock treated eight of his patients in this way. If a localized cystic condition is not present treatment in most of the remaining cases should be by obliteration of the pleura (pleurodesis) by a chemical pleurisy. Brock prefers silver nitrate solution for this purpose, a 20% solution may be swabbed on to the pleura at thoracoscopy or 5-10 minims (0.3-0.6 ml) of a 10% solution can be injected with an all-glass syringe. In either case it is important to aspirate air immediately after the treatment in order to get the pleural surfaces into apposition while they are inflamed. More than one injection may be required. This procedure gives rise to a reaction which may be severe, with pain and fever up to 100° F (37.8° C) or 101° F (38.3° C) for a few days. If a satisfactory pleural reaction is produced effusion will develop. Fifty-three patients in Brock's series were treated by pleurodesis, in three cases he used poudrage with talc by the method of Bethune,<sup>6</sup> but he found that silver nitrate was less disturbing and simpler to repeat after the initial thoracoscopy. Other substances, such as "gomenol" in olive oil, hypertonic glucose solutions, or blood, have been used by some workers. The principle of pleurodesis by chemical irritation in these cases seems well established, even though there is as yet no agreement about the most suitable agent for this purpose.

### RADIATION SICKNESS

Some of the immediate effects of radiation on the human organism are inhibition of enzyme action, death of dividing cells, changes in cell permeability, and reduced flow of saliva. To the patient the most unpleasant feature of radiotherapy is often the sickness which may make life miserable and interfere with treatment. The symptoms are nausea, with or without vomiting, and lassitude. The vomiting reflex is set in motion by abnormal stimuli to the afferent nerve endings, abnormal sensitivity of the reflex pathway at some point, or abnormal irritability of the muscles which are involved in vomiting. With nausea the same abnormalities are presumably present but below the necessary threshold to produce vomiting. Psychic factors have been suggested as the cause, but, while they may have an influence, no one with experience can consider that sickness due to the effects of radiation is not a real entity. The somatic changes must be chemical or nervous. There is no evidence, however, of a direct effect of radiation on the conduction of a nervous impulse. The possibility of inhaled toxic gases can be excluded with modern apparatus, and, since the vomiting frequently occurs when no radiation is given to the stomach or to any part of the reflex arc involved in vomiting it seems likely that endogenous chemical changes are responsible. Whether the chemical abnormalities in the blood reaching non-irradiated parts of the body are due to irradiation of the serum, changes

in cell permeability, actual breakdown of cells, or to the effects of irradiation on endocrine function is not known. The last is not a likely primary effect, since sickness can occur after irradiation of any part except the limbs, but it is possible that the chemical changes brought about by radiation might cause some hormonal disturbance.

The cause can probably be found in changes in the metabolism of cells which are sensitive to radiation. Sickness occurs most frequently after high doses to parts of the body which are very vascular, such as the neck, thorax, and abdomen. It has been noticed that quite small doses produce sickness in patients with lymphatic leukaemia and, to a less extent, myelogenous leukaemia, this suggests that the breakdown of blood cells, probably lymphocytes, may set free substances in the circulation which produce the vomiting. It is commonly held that histamine-like substances are primarily responsible for x-ray sickness, since tissue damage brings about their release. Indeed, histaminase has been used with moderate success as a remedy,<sup>1</sup> and "benadryl" has been reported as efficacious.<sup>2</sup> Kullander,<sup>3</sup> however, holds a contrary view. He found that the vomit of patients with radiation sickness is usually hypo- or achlorhydric, though test meals showed normal gastric hydrochloric acid after the sickness had passed off. He also found that the administration of 20-40 minims (1.2-2.4 ml) of 7% hydrochloric acid in water before meals and after x-ray treatment gave prompt relief. On the assumption that histamine would increase the secretion of hydrochloric acid he injected 0.125 mg of histamine before meals, this also relieved the symptoms. If the effects of radiation were due to histamine-like substances, presumably the symptoms would have been aggravated by the injections. Brick<sup>4</sup> has recently shown that large doses of radiation to the stomach (2,500-6,000 r) may cause damage leading to ulceration and perforation, necessitating partial gastrectomy in some cases. This complication did not develop until 2-3 months after the radiation, and it was not associated with any lowering of gastric acidity. X rays have been advocated by some authors for depressing gastric acidity during the treatment of peptic ulcer. Brick's work has demonstrated the danger of this procedure, and in any case, as Kullander has shown, acidity very quickly returns to normal after radiation. Any estimate of the value of remedies for radiation sickness must take account of the influence of secondary effects due to sepsis, loss of taste, interference with nutrition, and intestinal hyperactivity.

It has been claimed that many other remedies besides those already mentioned have given good results. Among these are sodium chloride, magnesium chloride, high carbohydrate diet, large amounts of fluid, vitamin C, vitamin B, and amphetamine. They have all had relatively short periods of popularity. A recent report<sup>5</sup> on the value of pancreatin again suggests that the mechanism of digestion is disturbed. Pyridoxin, given by mouth or intravenously, is at present the most popular and successful drug used.

for radiation sickness in this country. Maxfield<sup>6</sup> and his colleagues in the U.S.A. first used it for this purpose, and its value was confirmed later by others.<sup>7-8</sup> It counteracts the reduction in the white cells caused by radiation—vitamin C appears to have a similar action. Exactly how pyridoxin relieves radiation sickness is a mystery; the solution of which may be of great biological importance. If hydrochloric acid can produce the same good results, however, its cheapness and ease of administration should be in its favour.

### NYSTAGMUS IN PELLAGRA

Doctors who underwent the grim ordeal of caring for their fellow prisoners in Japanese prison camps were able to collect much interesting information on the effects of chronic malnutrition. Disabilities were observed which had not hitherto been recognized as due to dietary deficiency; these included retrobulbar neuritis and the painful condition described as "electric" feet. There has also been some evidence that malnutrition caused a number of other strangely assorted symptoms, including such oddities as troublesome nocturnal diuresis and the appearance of violet hallucinations when the prisoners attempted to read.

Some observations by Raadt<sup>1</sup> on prisoners of war in camps at Bandoeng, Batavia, and Pagan Barol suggest that a group of oto-neurological disturbances, presumably associated with the early stages of pellagra, should now be added to the other signs of malnutrition seen in these tropical camps. The symptom complex included vertigo, tinnitus, subjective deafness, headaches, nystagmus, and weakness of lateral gaze and convergence, but not all affected prisoners had all these symptoms. Apparently the most noticeable objective symptom was the nystagmus, which occurred in typical cases as a rhythmical to-and-fro movement of the eyeballs in a horizontal direction. In some prisoners the nystagmus was constant, but in others there were intermittent attacks which were often precipitated by attempts to look sideways or by changes in the position of the head. Such attacks were usually accompanied by vertigo and sometimes by vomiting. The vestibular system was tested by pouring ice cold water into the ears of prisoners with latent nystagmus or with active nystagmus which was checked by directing the eyes on a point beyond the range of oscillation. This procedure induced temporary nystagmus in normal subjects, but the irritability of the prisoners was abnormally high and the test often caused vertigo, sweating, vomiting, headaches, and even diarrhoea and fainting. Further tests in which the subject was turned round on a stool led to such unpleasant consequences that the prisoners became unwilling to co-operate. Less disturbing, however, were walking and pointing tests and these often revealed abnormalities.

It might at first sight appear that the nystagmus was due to a peripheral nerve lesion, but the fact that some prisoners had nystagmus without defective hearing was taken as evidence against this view. A disturbance in the central nervous system, presumably involving the vasomotor reactions of the brain stem, seemed a more probable explanation of the symptoms. Raadt was unable to examine the composition of the diet or to test the curative action of nutrients suspected of being deficient, but he points out that vertigo is well recognized as a frequent and early feature of pellagra while American workers<sup>2,3</sup>

have also mentioned nystagmus as an occasional symptom. It seems probable that the early stages of pellagra are often overlooked or mistaken for neurasthenia. In the fully developed disease the attention of the clinician is so occupied in treating the familiar dermatitis, diarrhoea, and delirium that vestibular abnormalities would be of minor interest even if the patient was in a fit state to be examined. It is perhaps understandable, therefore, that early oto-neurological abnormalities should hitherto have attracted little attention.

### PULMONARY ARTERIOVENOUS FISTULA

Pulmonary arteriovenous fistula, in which there is a shunt of blood from pulmonary arteries to veins, is a congenital condition which has been recognized during life only a few times. In a recent paper Barnes<sup>1</sup> and his co-workers mention that they have found reports of 23 cases and they add two of their own, but wider knowledge of the existence of the condition may show it to be much more common than this figure suggests. The conspicuous outward signs are cyanosis, polycythaemia, and finger clubbing, with the result that congenital heart disease or polycythaemia rubra vera might be mistakenly diagnosed. The ascertainment of a pulmonary arteriovenous fistula is not merely of academic interest but practically important, since pneumonectomy can restore the patient to normal health. Burchell and Claggett<sup>2</sup> have described a successfully treated case and reviewed eight others recognized clinically, four of which were also cured by surgical excision.

An analysis of these reports shows a stereotyped syndrome, with dyspnoea, dizziness, and haemoptysis as the commonest symptoms and cyanosis, clubbing, and polycythaemia the typical signs. The heart is usually not enlarged, but on radioscopic examination one or more nodular pulsating shadows will be seen in the lung field with increased hilar pulsation on the side of the lesion. Most of the patients have had small capillary haemangiomas of the skin or mucous membranes, and these should provide a valuable clue to the existence of the pulmonary lesion. A murmur either systolic or continuous as in patent ductus arteriosus is sometimes heard on the chest wall. The red cell count is 6 to 9 million with a haematocrit finding of 60 to 80% erythrocytes and an increase in blood volume. The arterial haemoglobin-oxygen saturation in the four cases in which this was determined was the same in all—namely, about 70%.

Such unvarying results are regarded by Burchell and Claggett not as a chance occurrence but rather suggesting a compensatory mechanism which by an increase of cardiac output holds the arterial oxygen tension at a certain necessary level. However, they do not report any estimation of cardiac output in their patient, and, as Taussig and Blalock<sup>3</sup> have pointed out, very low arterial oxygen saturation shows the absence of any such mechanism in the tetralogy of Fallot. After pneumonectomy the polycythaemia quickly disappeared in Burchell and Claggett's case and in the case successfully treated by Barnes and his colleagues. In the latter the red cells numbered 9.5 million per cmm before operation, a week after operation the figure had fallen to 6.4 million, and ten days later it was 5.4 million. There should be no difficulty in correctly diagnosing this condition if it is borne in mind when the conspicuous symptoms are those which at first sight suggest congenital heart disease, polycythaemia rubra vera, or chronic lung lesions accompanied by cyanosis.

## THE ORIGINS OF CARDIAC PAIN

Fifty years ago Huchard<sup>1</sup> drew up a list of eighty theories which might account for cardiac pain, facts have since disproved most of them. It is now the general opinion that both cardiac effort pain and the pain of myocardial infarction are the result of myocardial ischaemia. There is extensive evidence, conveniently summarized by Fishberg,<sup>2</sup> to support this theory. Thus, induced anoxaemia tends to provoke anginal pain, and the transitory changes in the electrocardiograph are of the same type in coronary thrombosis, coronary arteriosclerosis, experimental coronary obstruction, and induced anoxaemia. Sutton and Lueth<sup>3</sup> concluded from animal experiments that the pain of coronary occlusion was due to myocardial ischaemia, though there is also a possibility that pain can arise from direct stimulation of the nerve plexus surrounding the coronary arteries.<sup>4</sup> Further support is given to the anoxaemic theory by the well-known fact that obstruction of the blood supply to skeletal muscle during exercise produces severe pain, relieved by rest or removal of the obstruction.

Recently there have been suggestions that cardiac pain can have other origins. Hirsch and Orme<sup>5</sup> take anatomical facts into consideration, and Wyburn-Mason<sup>6</sup> in this *Journal* argued mainly on clinical grounds. The former suggest that cardiac pain arises in and about the coronary arteries rather than in the muscle tissues in the same way as pain occurs with sudden thrombosis of a peripheral artery. They draw attention to the many myelinated nerve fibres which are distributed in the fibrous tissues along the coronary arteries and which terminate in the walls of these arteries. They believe these nerves are sensory, and they refer to a similar pattern of sensory innervation which has frequently been described in peripheral systemic vessels. To support their theory they mention the conclusion of Katz and his colleagues<sup>4</sup> that in experimentally induced coronary artery pain the sensory response was due not to occlusion of the coronary artery but to direct stimulation of afferent fibres around the coronary vessels. These anatomical observations can hardly be used as evidence against the theory that cardiac pain is due to anoxaemia, at the most they indicate other possible mechanisms. All non muscular tissues of the heart have a rich sensory innervation, and in animal experiments cardiac pain appears to arise both from direct stimulation of coronary nerve plexuses and from local anoxaemia. It seems reasonable to suppose that in man the nerve plexuses can act either as a path for pain or as a starting-point.

In putting forward what he called "a new conception" of angina pectoris Wyburn-Mason described a number of cases in which anginal pain occurred without any abnormality of the heart. He added a list of conditions in which angina and vasodilatation, local or general, are said to coincide, and, interpreting this coincidence as a causal relationship, he suggested that the common factor which gives rise to anginal pain in coronary artery disease and in disease of neighbouring tissues is vasodilatation. Unlike Hirsch and Orme, he considered that the fibres which conduct the protopathic pain impulses are the unmyelinated vasodilator fibres which run by way of D1-5 posterior nerve roots, fibres which supply the mediastinal tissues including the heart. Any excess of vasodilator impulses in these nerves might lead to abnormal nervous activity and therefore pain impulses. Discussing angina of cardiac origin, Wyburn-Mason suggested that during increased

cardiac activity the afferent nerve endings are stimulated by metabolites which collect because coronary sclerosis prevents vasodilatation. The presence of these metabolites causes abnormal reflex impulses in the coronary vasodilator pain fibres, and the immoderate attempt at vasodilatation gives rise to pain.

Although the concept of frustrated vasodilatation being painful in this manner is a novel one there seems little else to recommend it. To the same category belongs the theory that although accumulated metabolites stimulate the nerve endings of pain yet they cause pain only through the excess of reflex antidromic impulses. Many problems connected with angina remain unsolved, no doubt it may develop in the absence of cardiac disease or be absent in the presence of gross myocardial ischaemia, but it still does not seem possible to approach nearer to the truth of the matter than Fishberg's summing up, that angina pectoris is the cry of the heart for more oxygen.

## THE NATURE OF SEBUM

It is about 300 years since Malpighi first described the sebaceous glands. Boerhaave added to this description, but it was not until the latter half of the nineteenth century that much interest was taken in their function. In our own time some authorities have suggested that nervous and endocrine factors influence the secretion of sebum, but few quantitative observations have been made. Schur and Goldfarb<sup>1</sup> in 1927 estimated the quantity of sebum secreted on the forehead by wiping with small cotton wads the area of skin to be tested. They found that the layer of sebum on the surface of the skin reappeared very rapidly, often within 15 minutes of its removal, but did not exceed the original amount even after an interval of two hours. They therefore concluded that the amount of sebum over a given area of skin was constant and that secretion stopped when a certain level was reached and started again when the amount fell below that level. Emanuel<sup>2</sup> confirmed this observation and found that isolation of the area for one week produced no increase in the thickness of the layer. This was not constant but varied from day to day within a range characteristic for a given area. He concluded that the thickness was regulated by an interaction between two opposing factors: the resistance of the sebaceous layer and the functional capacity of the glands. The former was proportional to the thickness of the layer and the consistency of the sebum and the latter depended upon the size of the glands. The rate of reproduction of the layer appeared to be dependent upon the number of glands in the area in question. Dunner<sup>3</sup> also concluded that the sebum level was dependent on the viscosity of the sebum. He showed that a rise in external temperature raised the productive capacity of the glands and the thickness of the sebum layer.

Recently Butcher and Parnell<sup>4</sup> have made some interesting observations on the quantity and composition of sebum secreted on the heads of three individuals of different type. In one man with a dry scalp and dandruff there was an average of 0.168 mg of fat and 0.0171 mg of cholesterol per sq cm when specimens were taken once a week over an eight-week period, the cholesterol being 9.4% of the total sebum. In another man with an oily scalp and sparse hair there was an average of 0.219 mg of fat and 0.0149 mg of cholesterol per sq cm over the same period, 6.3% of the total sebum being cholesterol. In the third man, with good hair and little dandruff, there was an

<sup>5</sup> *The Hair and Scalp* 1944, London.

average of 0.160 mg of fat and 0.0119 mg of cholesterol per sq cm the cholesterol being 7% of the total sebum. When collected daily there was only slightly less sebum for a given period than when collected weekly, and frequent removal of the sebum did not cause increased oiliness of the scalp.

In the past there has been some doubt whether sebum contains cholesterol, though Savill<sup>2</sup> mentions it as being present. In Butcher and Parnell's cases the highest content of cholesterol occurred in the individual with the greatest desquamation of the scalp. Had the cholesterol originated in the desquamating cells, then the collection made weekly should have contained the greatest proportion of cholesterol, but this was not the case. Butcher and Parnell also investigated the effects of resistance on the secretion of sebaceous glands. They found in the rat that when the skin was covered, or a resistance created, the gland did not become smaller but enlarged from accumulation of cells and sebum within it. This accumulation is similar to that present in sebaceous cysts.

### THE COURSE OF RHEUMATOID ARTHRITIS

In few diseases is it more difficult to form an unbiased opinion about the value of different methods of treatment than in rheumatoid arthritis. Its onset may be acute or gradual, and remissions or exacerbations occur for no obvious reason, remedies which have proved helpful in one case are perhaps ineffective or even harmful in another. In some cases the condition becomes quiescent for months or years and then relapses, while in a proportion variously estimated at 50% to 70% the disease is permanently arrested, though often severe crippling deformities remain. Two hundred and fifty patients who received only simple medical or orthopaedic treatment for rheumatoid arthritis have been studied by Short and Bauer<sup>1</sup> at the Massachusetts General Hospital over a long period of years. They point out that in nearly all similar investigations the details given have been insufficient to make comparisons practicable. They have therefore evolved a system of observation and record which might be used as a standard. The course of the disease must be followed in many more cases before definite conclusions can be reached, and general practitioners could well undertake some of the necessary research, since they have their patients under constant observation and it would not make excessive demands on their time or require special training or equipment.

The results of Short and Bauer's observations confirmed certain general impressions. Their patients were admitted to hospital between 1930 and 1936, in all of them the usual physical signs of rheumatoid arthritis were present. They generally remained in hospital for three or four weeks for investigation and for instruction in simple remedial measures which could be carried out at home, including appropriate diet and physiotherapy. Thereafter they reported back to the hospital once or twice a year if practicable or they were interviewed by trained observers and their condition noted. When necessary they were re-admitted to hospital for special treatment. The average duration of observation was 9½ years, with a range from six months to 16 years. In slightly over 50% improvement took place, and complete recovery in 15%. Fifty-two patients were given fever therapy and 16 had blood transfusions but in neither of these groups were results better than in the cases which had no special treatment. Of those who improved within two years 37% later relapsed compared with 28% of recorded relapses in a combined series taken from the literature, of 768 patients who originally improved with gold therapy.

Investigations of this type will always be complicated by the fact that in the course of rheumatoid arthritis outside influences may turn the scale one way or the other. The mere fact of being under regular observation has an encouraging effect, and the suggestion that therapeutic resources have been exhausted does much to weaken the patient's power to fight the disease. One American authority with wide experience has said that though he is doubtful if vaccines have any specific effect he uses them in small doses in order to keep the patient under continual observation and thus control the general line of treatment.

### ARSENIC AS A CAUSE OF CANCER

Prolonged arsenical therapy can cause cancer of the skin and other organs, and there is a risk of occupational cancer among workers making arsenical compounds. Sir Jonathan Hutchinson in 1887 was the first to draw attention to the development of cancerous ulceration on keratoses following the use of arsenic in the treatment of psoriasis. Though arsenic was used widely to treat skin diseases, syphilis, and many other general diseases it would seem that in psoriasis there is some particular predisposition to this grave complication of treatment. Apart from the more obvious forms of cancerous ulceration, superficial scaling and keratotic lesions and multiple small intra epidermal carcinomata of a benign type are often seen, more particularly on covered parts. The lesions may remain stationary, or involute, or they may progress to more malignant forms.

These changes may appear within a few years of the beginning of treatment or exposure, or they may be delayed up to 40 years. In a comprehensive review of the subject Neubauer<sup>1</sup> states that an average interval is 18 years. Arsenic is a normal constituent of body tissues, and small amounts may be found in skin, hair and nails, and urine, the quantities vary slightly with the geographical situation, the character of the drinking-water, and other factors. The finding of arsenic in the tissues, therefore, is not necessarily significant when the cause of a cancer is being considered. Neubauer states that the results of chemical investigation are disappointing, definite conclusions cannot be drawn either from the absence of arsenic from the tissues or from its presence in small amounts. Animal experiments have produced only doubtful results, and further knowledge of the pathogenesis of arsenical cancer may not be obtained until the pharmacology of arsenic is better understood. Barry, Bunbury, and Kennaway<sup>2</sup> have suggested that arsenic may induce cancer not by direct action but by causing accumulation in the tissues of organic (carcinogenic) compounds which would normally be oxidized or reduced to other forms. Occupational cancer of the skin and lungs has been reported in workers engaged in factories producing sheep dip and insecticides, and in rare instances cancer of the skin in gardeners and in metal-miners and smelters has been attributed to arsenic.

Sir Reginald Watson-Jones will deliver the Robert Jones Lecture on "The Reactions of Bone to Metal" before the Royal College of Surgeons of England (Lincoln's Inn Fields, London W.C.) on Thursday, Dec 9, at 5 p.m.

Dr W. H. Wynn, F.R.C.P., will deliver the FitzPatrick Lectures on "The Pestilences of War" before the Royal College of Physicians of London (Pall Mall East S.W.) on Tuesday and Thursday, Dec 7 and 9, at 5 p.m. In the first lecture Dr Wynn will speak on "The Early Civilizations and Greece," and in the second on "The Roman Republic and Empire."

## THE INSTITUTE OF OPHTHALMOLOGY

The Institute of Ophthalmology one of the federated institutes of the British Postgraduate Medical Federation in the University of London, was opened formally on Nov 4. The buildings of the Central Eye Hospital in Judd Street, King's Cross, have been largely reconstructed internally to serve the Institute. The Institute has grown out of the medical schools of the three amalgamated hospitals—the Central Eye Hospital itself Moorfields and Westminster. These schools have been in existence for many years, the one at Moorfields dating back as far as 1810.

The work to be carried out at the Institute will be twofold—postgraduate teaching and research both in laboratory work and on clinical material. Teaching will be available to qualified students from all over the world who wish to train as specialists in ophthalmic medicine and surgery. It was stated that at the present time students from seven countries, not including the British Isles, are taking courses at the Institute. For the present term 126 students are enrolled. Three main research teams of the Medical Research Council are carrying on work there. They are an ophthalmological research unit working under Sir Stewart Duke Elder on the physiology of the eye and ocular diseases, a vision research unit under Professor H. Hartnidge, and an industrial illumination unit working under Mr Weston on the practical aspects of lighting. In addition the Institute may be made available for individual research. There are also a pathological department, which carries out all the routine bacteriological and histological work of the hospital and conducts research in these fields, and a department of medical illustration, which includes a well-equipped photographic studio with dark-rooms, photomicrographic apparatus, and printing facilities. The ophthalmological library and museum are said to be the most complete of their kind in any country. Great skill has been shown in adapting the old hospital buildings to this new function.

The Earl of Rothes, chairman of the committee of management who presided over the opening ceremony, referred to the help of the British Postgraduate Medical Federation in sponsoring this enterprise. Sir John Herbert Parsons spoke of the high reputation of the three hospitals as teaching schools and said that in the new Institute this tradition would be enhanced because the teaching would be carried out under much more favourable circumstances. The large amount of research already done by the staffs of the hospitals would be continued on a wider basis. The Institute would be under the supervision of Sir Stewart Duke-Elder and this fact alone would ensure its success.

### Greetings from America

Professor Alan Woods, director of the Wilmer Institute, Johns Hopkins University School of Medicine brought the congratulations of American ophthalmology, and said that the founding of such an Institute was the rational outcome of long and industrious work in ophthalmology in Great Britain. The independent or semi-independent hospitals in Europe and America had provided a good basis for present and future service, but a new type of institution was needed for research and the advancement of the frontiers of knowledge. Most of the obvious things had been done and modern ophthalmic research must include the application of biophysics, bacteriology and related sciences to the study of the normal and the abnormal eye. But advances along these lines could not be made unless the scientists undertaking the work were specially trained, and the help of biochemists, biophysicists and others was needed. In short new types of investigators were required.

The type of institute now being dedicated afforded the answer to this quest. Ophthalmological research must be a university undertaking, so that the investigation could be co-ordinated access made possible to clinical material and fellowship offered with colleagues in other branches of medicine. In a university school of medicine an ophthalmological institute must be regarded as an integral unit. It was typical of British courage to undertake this task in the midst of so much other reconstruction. Anything which his own school of medicine could do to assist would be only a small acknowledgment of the debt it owed to British ophthalmology. He extended to the new enterprise good wishes for success and high achievement.

Greetings were also given by Professor H. J. M. Weyve of Utrecht who said that this was a great day not only for ophthalmology in London but throughout the world. Ophthalmology could not be looked upon as a science apart from the rest of medicine, all parts were interlocked, and the fact that the Institute was part of the University of London showed that that was recognized in this country. England had contributed much to the study of this specialty through many of its distinguished workers, notable among whom was Sir John Parsons.

It was stated that the amalgamated hospital is the largest specialist eye hospital in the world and the Institute the first of its kind in Europe. The practice of the hospital, drawing as it does patients from the entire London area and indeed from all over the United Kingdom, provides material for teaching and research which is unrivalled in any country.

Later in the day Professor Alan Woods delivered the inaugural lecture on experimental studies on the pathogenesis and therapy of ocular tuberculosis.

## Preparations and Appliances

### A SCROTAL BANDAGE

Mr B. JOHN MAXWELL, a student at the Liverpool University Medical School, writes: Several excellent methods of bandaging the scrotum are already in everyday use. Prominent among them are the roll bandage, the T bandage, and the Bellevue adhesive plaster methods.

The roll bandage method is simply the winding of a figure-of-8 with a 4 in (10 cm) bandage so that the legs are through

1—Wool pad shown in position with rolled apex supporting the scrotum. 2—Roll bandage threaded through apical hole. 3—Roll bandage brought to and threaded through the basal holes. 4—Bandaging completed, showing bandage following fold of buttock upward and forward. 5—Complete. 6—Showing position of holes and direction of bandage.

the loops the loops are held up to waist level by alternate complete turns round the abdomen. In applying a T bandage the joint should be at the back, the stem of the T coming between the legs from the back and up to the front to give support to the scrotum. In the Bellevue method a piece of 'elastoplast' 36 in by 4 in (90 by 10 cm) has two mid-width slits cut from each end, but not to meet at the centre. This gives an H-shaped piece, the bar of which is padded with gauze and applied to the scrotum in such a way that the two upper limbs of the H are passed either side of the penis.

and applied to the abdominal wall and the two lower ones curve laterally following the folds of the buttock. The outpatient who requires daily scrotal dressings is however, still a problem as the roll bandage and the T bandage methods need great skill and take a certain amount of time if slipping, rolling and rubbing are to be avoided, while the Bellevue plaster is extremely painful to take down each day.

The method described below has the advantages that not only does it give comfort, support and security, but it is easy to put on taking little time, and it need not be removed for defaecation. All that is required is a triangular bandage a 3 in (7.5 cm) bandage, cotton wool, and some 1-in (2.5 cm) adhesive tape.

The patient lies on his back and the dressing is applied to the scrotum. A triangle of wool has its apex rolled up into a firm pad which is placed underneath the scrotum acting as a support, and the rest of the triangle of wool covers the scrotum so that the base of the triangle reaches the peno scrotal junction (Fig 1).

The triangular bandage has a piece of 1-in adhesive tape stuck on to it about 2 in or 3 in inside the apex and a slit cut into it (the plaster is only to reinforce the edges of the hole in the bandage). The triangular bandage is now placed over the wool, again base upwards, so that the apical hole lies in the crotch posterior to the wool pad. Two more pieces of adhesive plaster are stuck on to the triangular bandage 1 in above and medial to the anterior superior iliac spines and slits cut into them (Figs 3, 5, and 6).

The basal corners are now tied round the back and 2 ft (60 cm) or more (depending on the obesity of the patient) of the roll bandage is threaded through the apical hole (Fig 2). The bandage is drawn back between the legs and laterally, following the folds of the buttock upward and forward (Fig 4), deep to the triangular bandage, to the basal holes, through which it is threaded (Fig 3). The roll bandage is now taken across the back and wound round the body over the triangular bandage (Fig 5). The end is strapped down with adhesive tape. To complete the bandage a hole is made through which the patient can micturate.

Important points are: (1) Before tightening the bandage by traction on the apex the scrotum should be drawn upwards. This, together with support from the wool pad, gives 'lift' to the scrotum. (2) The basal holes should not be made until they have been tried for position. (3) The lines of pressure lie between the three holes, therefore it is essential that the wool should extend beyond the pressure lines to prevent rubbing. (4) The patient should be allowed to decide where he wants the hole through which he will micturate.

The completed bandage is neat and comfortable and needs little skill in its reapplication.

I would like to thank Professor C. A. Wells for his advice and criticism and for the services of his artist.

The Nurses and Midwives Whitley Council have agreed on new training allowances, which will take effect from Sept. 1, for student mental nurses employed in the National Health Service. They are regarded as the basis on which true student status can be built up, bringing mental nurse training more closely into line with training in other professions. The responsibilities resting upon student mental nurses and the exacting nature of the work in mental institutions are recognized in the allowances payable to them. Men and women will receive the same training allowances. Additional dependants' allowances will be paid to help those with family responsibilities. For students recruited on or after Jan. 1, 1949, the first-, second- and third year allowances will be £230, £240, and £255 respectively. Students will also receive proficiency allowances of £20 and £30 respectively on completing the second and third years of training if they pass the appropriate examinations. Students who live in accommodation provided by the employing authority will pay £100 a year for board and lodging. For existing female and resident male students or such students recruited before Jan. 1, 1949, the allowances with effect from Sept. 1, 1948, are £130 in the first year, £140 in the second year and £155 in the third year, the emoluments being valued at £100. These students will also continue to receive proficiency allowances. Uniform will continue to be provided and laundered without charge for all students. Non resident students will also receive free meals on duty. Where in exceptional cases existing salaries are higher than the new allowances students will be entitled to retain them. These scales represent an increase of £30, £40 and £50 per annum respectively on the previous basic rates for female students. The additional annual cost to the National Health Service will be in the neighbourhood of £65,000. The settlement has been accepted by the nurses' representatives on the understanding that a special committee of the Council will be set up to consider the working conditions in mental hospitals and to recommend measures necessary to achieve full student nurse status as soon as possible. The management side have agreed to take all measures in their power to put into force any recommendations on the matter adopted by the Council.

## Correspondence

### The Training of a Doctor

SIR—The comments in this letter are inspired by Professor J. A. Ryle's letter (June 12 p. 1153). In this he rightly deplores the lack of attention given to psychosomatic medicine in the curriculum. Herein I believe lies the pointer to the future development of general practice as we understand the term. All thinking members of our profession must be depressed when we consider the future of the general practitioner. We are all conscious of the development of the type of practitioner who takes progressively less and less clinical responsibility who spends his day prescribing medicine, and promptly refers all sick patients for either indoor or outdoor hospital supervision. I greatly fear that the general practitioner of the future is menaced by this degradation of his professional function into a signer of forms and a director of patients to an appropriate hospital department.

There is, however, a dignified and academically honourable alternative. I feel strongly that the general practitioner as we know him should develop into a sound psychosomatic physician. He must certainly retain his character of family physician. This tie will in fact be tightened rather than slackened as a result of his training in psychosomatic medicine. He will be equipped as few general practitioners are at present to explore that vague hinterland of medicine where the organic and the functional join hands to play such havoc with his patients. A more intimate knowledge of organic medicine will be necessary than that of the present general practitioner, perhaps a standard intermediate between that of the present practitioner and the standard required for membership of the Royal College of Physicians.

Such a standard is by no means beyond the capacity of the average medical graduate, since he will be relieved of the obligation of being in addition surgeon, gynaecologist, and obstetrician to his patients. These functions must be left in the hands of more capable performers than the average general practitioner. It has been well said that no operator should open an abdomen to remove a simple appendix unless he is prepared to remove a foot of bowel if necessary. The general practitioner must face up to the ultimate loss of surgery, gynaecology, and obstetrics. However, I see his status increased rather than diminished by the development outlined above.

This professional keystone to the arch of medical service must be vested with great authority and responsibility. With apologies for mixing my metaphors, he must be the captain of his patient's ship of health, deserting or sharing the bridge for brief interludes only while the surgical or other specialist pilot negotiates his own highly localized reefs and channels. From his ranks will be drawn the most able, to become the consulting and teaching physicians as we know them to day, but with this difference that they will have graduated from the ranks of psychosomatic family physicians rather than from the medical registrars of teaching hospitals, a consummation devoutly to be desired.

It may be objected that there will always be a need for the all rounder type of doctor in the outlying country areas. This will be true only to a very limited extent. I feel sure that, with the aerialization of transport, surgery, gynaecology, and obstetrics will increasingly be relegated to institutions even for country patients.

To summarize, I feel that the present trend in medical practice is on the one hand the production of specialists with a much too academic background, and on the other hand the professional degradation of the general practitioner to a glorified medical clerk. This general trend is most deplorable and I suggest the development outlined as a logical and dignified alternative—I am, etc.,

Sydney, Australia

LANCE HEWITT

### Surgical Treatment of Ménière's Disease

SIR—In an annotation on the surgical treatment of Ménière's disease (Nov. 6 p. 829) you kindly referred to the operation I employ for the relief of vertigo in suitable cases, saying, 'This cures the vertigo without affecting the hearing.' I have always found<sup>2</sup> that this operation which consists in removing all or part of the membranous external semicircular canal, is followed

by total and irreversible loss of cochlear as well as vestibular function on the operated side

For this reason it is reserved for cases in which the disease appears to be unilateral and the hearing on the affected side is seriously impaired and, as a rule, distorted. Such distortion is a characteristic and common feature of the deafness in Ménière's disease, it is particularly noticeable for musical and high pitched sounds, and when present adds to the distress of the disease.

I have found that the loss of a distorted remnant of hearing in one ear, far from diminishing the general capacity for hearing, often leads a patient after an operation to say that his hearing is better because once again he can enjoy listening to music, and loud sounds no longer distress him. Thus whilst it is often true to say that the hearing capacity of patients subjected to my operation is altered, sometimes for the better, I would like to make it quite clear that the hearing in the operated ear is always lost, though for reasons already given such a loss often proves to be a gain—I am, etc.,

London W 1

TERENCE CAWTHORNE

#### REFERENCES

- <sup>1</sup> *J Laryng* 1943 58 363  
<sup>2</sup> *Ann Otol etc St Louis* 1947 56 18

SIR,—In the annotation (Nov 6, p 829) on surgical treatment of Ménière's disease you state that Cawthorne's operation cures the vertigo without affecting the hearing. In one or two cases Day has succeeded in coagulating the labyrinth with retention of some of the hearing, but destruction of the labyrinth by any other method devised up to the present has involved destruction of the cochlea also.

The object of the operations devised to deal with the labyrinth itself was to avoid an intracranial operation but the neurosurgeons, until Ray's recent paper, had claimed that the destruction of the vestibular portion only of the eighth nerve left satisfactory hearing. It is now generally recognized that the hearing remaining after Dandy's operation on the vestibular nerve is not satisfactory in most cases, and the risks involved are not merited by the results achieved—I am, etc.,

Lincoln

M SPENCER HARRISON

SIR,—The paper on Ménière's syndrome by Mr E R Garnett Pisse and Dr J S Seymour (Nov 6, p 812) prompts me to raise two points. The first relates to the case Ménière described in 1861. "It would seem," the authors state, "that acute haemorrhagic labyrinthitis was the cause of the syndrome. So far so good—but it is in my view essential to add that in the original and fatal case Ménière's syndrome has to be interpreted as a haemorrhagic symptom of acute leukaemia."

This leads to my second point. The organ of hearing (inner ear) and the organ of equilibrium (labyrinth) live in a semi-detached dwelling. These and their two cranial nerves (the cochlear and the labyrinthine nerve) are affected by a great variety of causes with the common feature that all can produce Ménière's syndrome. The outlook in Ménière's disease accordingly varies from death within a few days to complete recovery.

The term "Ménière's disease" is at present one of the vaguest in medical terminology and to replace it by "Ménière's syndrome" has not helped to reduce the muddle. I believe that we should either discard the term altogether or agree that we mean something entirely different by it than Ménière meant to describe—namely, a haemorrhagic labyrinthine symptom.

Before recommending sweeping therapeutic measures we must try to group these greatly differing cases according to their proved or probable aetiologies and in this respect we are still very much at the beginning. Ménière's so Pisse and Seymour complain "had inadequate knowledge of the true aetiology. Alas so have we. Surgical suggestions for the relief of symptoms of varying and obscure aetiology are at best initially successful. In the case of Ménière's disease they have included many different procedures among which operations on the antra. So far they have all had one thing in common—they have not come to stay—I am, etc.

### Intussusception Due to Carcinoma of Colon

SIR,—Intussusception of the gut at either extreme of life is a fascinating lesion, and Mr R A C Owen's account of two cases of colonic intussusception due to a carcinoma (Oct 30, p 786) will be of interest to all surgeons. He raises three points of some academic importance with which I am not in entire agreement. In the first place I do not think that the condition is so rare as the published figures would indicate. In a limited surgical experience I have come across three cases of this type, and I think that most surgeons meet with at least one or two examples during their career. Moreover, it is not uncommon to find that a growth felt on rectal examination in the out-patient department proves to be in the lower pelvic colon when seen at operation, these are undoubtedly examples of recurrent intussusception of minor degree.

Then Mr Owen suggests that colonic intussusception in adults is not necessarily associated with a carcinoma, but surely any other cause must be a rarity. In dealing with a colonic intussusception one looks for and expects to find a carcinoma, or at any rate a growth of some kind. I agree that occasionally a tumour is absent, and in one of my patients, who was a British soldier serving in India, no abnormality was found in the transverse colon, which had intussuscepted and was subsequently resected. Possibly his intussusception was due to the uncommonly active gastro-colic reflex from which most newcomers to the Tropics suffer and akin to the spate of intussusceptions which are said to afflict those of Mohammedan faith during the fasting season.

Finally, it is not strictly accurate to say that this condition is of necessity associated with a long and mobile pelvic colon. The essential feature is a mobile colon, and whilst the fulfilment of this requirement is usually confined to the transverse and pelvic portions of the large bowel it occasionally happens that the ascending colon also has a mesentery owing to faulty fixation of the gut to the abdominal wall during development, in the presence of an exciting factor this may result in an ileo-caecal intussusception. In a remarkable case at present in Mr W J Ferguson's wards at the West Middlesex County Hospital a woman of 75 was subjected to laparotomy on account of symptoms of acute upon chronic intestinal obstruction. An intussusception of the colon was found lying below the spleen. It reduced with ease and proved to be of the ileo-caecal type. The whole colon from caecum to rectum was attached to the abdominal wall by a long mesentery, making a hemicolectomy a matter of extreme ease. The exciting factor producing the intussusception was a small papillary carcinoma encircling the ileo-caecal valve—I am, etc.,

Isleworth, Middlesex

LOUIS A IVES

SIR,—Mr R A C Owen in his paper on the subject of intussusception in adults due to carcinoma of the colon (Oct 30, p 786) states that only two such cases have been reported in the literature in the last ten years. The following case would therefore seem worth recording.

A woman aged 74 was admitted to hospital in the evening of June 6, 1948, complaining that something had "come down" when she was straining at stool that afternoon. Her previous history was that after being constipated all her life she had had diarrhoea with three or four motions every twenty-four hours for two months before admission. No blood or slime was noticed in the stools. She had had a ruptured pnenum in childbirth forty years ago. On examination she was a thin old lady. Examination of her abdomen was negative. A large intussusception was projecting five to six inches from the anus, with an annular papilliferous carcinoma at its apex. The intussusception was reduced to within the rectum, with the patient in the left lateral position, without an anaesthetic. The buttocks were strapped together and the patient was placed on her face with the foot of the bed raised to complete the reduction. On June 21 a laparotomy was performed through a right lower paramedian incision under a general anaesthetic. The growth was found to be in the sigmoid colon, and as there was no evidence of secondary deposits the sigmoid colon was resected with end-to-end anastomosis. After operation she did well and was discharged from hospital on July 19. When last seen, on Oct 17, she was very well, with no symptoms at all.

The pathological report on the specimen was as follows: "The specimen consists of large bowel, 20 cm in length. In the centre is a flattened papilliferous growth, 7 cm in diameter, which com-

the serous envelopes the bowel wall it appears to be confined to the mucosal coat. Microscopic structure the tumour is a well differentiated adenocarcinoma.

My thanks are due to Mr Donald Barlow, who performed the operation and has given permission for me to report the case—I am etc

H BERNARD JUBY

### Purpura Fulminans Complicating Scarlet Fever

SIR—I have read with great interest the article by Drs T Anderson, M S Ferguson, and J B Landsman in the *Journal* of Sept 18 (p 549) entitled 'Purpura Fulminans Complicating Scarlet Fever'. This work poses clearly the problem of pathogenesis of the haemorrhagic forms at the onset and of the haemorrhagic complications either generalized or localized, in infectious diseases.

It is difficult to explain the aetiology of these haemorrhagic complications. It cannot be explained on the grounds of specific virulence of the organisms, because in time of epidemics only a small number of patients are affected by these grave forms. The same can be said of the organisms responsible for reinfection or cross infection so frequent in hospital environment and which very fortunately give rise to haemorrhagic manifestations only occasionally. We have therefore to admit that the affected subject responds in some peculiar way to the causative organism.

It has been frequently said that these haemorrhagic manifestations are of allergic nature. This interpretation is very unlikely, whether it be concerned with allergy towards the responsible organism of the primary disease or with hetero allergy—viz purpura allergy as defined by Moro and Keller—to a different organism. Allergic manifestations usually do not show these dramatic features of the haemorrhagic complications in specific fevers, they do not cause such intense vascular lesions, they are in general not so serious, and lastly, tests for allergy to the organisms incriminated have been uniformly negative.

It is my belief that the haemorrhagic syndrome observed by Drs Anderson, Ferguson, and Landsman can be compared to the Sznarelli-Shwartzman phenomenon. A given infection can give rise in certain individuals to a transitory alteration of bodily response (*alteration reactionnelle transitoire*) analogous to the response in the rabbit which has received a preparatory injection of a filtrate of organisms in the experiments of Sznarelli and Shwartzman. If at that precise moment the precipitating factor comes into play (this being either a persistent primary infection or a cross infection or even chemotherapy) the result may be a haemorrhagic manifestation either generalized or localized unrelated to the intensity, gravity, or nature of the precipitating factor.

The haemorrhagic phenomenon has indeed nothing specific in itself and can be produced by various agents, a fact which is responsible for the belief that the real cause is sometimes chemotherapy, in others the persistence of an infection or septic focus or in others a cross infection. Moreover, two facts in the case of Dr Anderson and his co-workers are of special interest. (1) Marked hypothermia—Sznarelli has produced experimentally in the animal a syndrome with hypothermia and haemorrhagic signs. (2) The spectacular action of penicillin can be compared to the specific immunization which neutralizes the toxin from the filtrate of bacilli as shown in the Shwartzman phenomenon, the toxin having been rapidly neutralized haemorrhagic manifestations do not occur.

In a series of papers, partly yet unpublished I have shown the importance of the Sznarelli-Shwartzman phenomenon in human pathology with special reference to infection and chemotherapy. I have included all these facts under the general denomination of *sanergy* ('*sanergie*') and I believe that this new interpretation of a great number of facts of, until now obscure significance will lead to search for rational treatment—I am etc

Hopital Rothschild Paris

S LEWIS

### Bornholm Disease

SIR—On Oct 4 a little girl aged 16 months was brought to me. She groaned with arch expiration inspiration was short and shallow she looked anxious the temperature was 100 F (37.8 C) the upper abdomen was rigid and I could find

no abnormal signs in the chest. Her mother reported she had been quite well the previous day and until suddenly attacked with pain at 5 p.m. on that day, but that she had had a similar attack on Oct 2 from 11 a.m. till 6 p.m.

This child was sent to hospital as a matter of interest with a tentative diagnosis of Bornholm disease. In hospital she was to my mind unfortunately given sulphamezathine and penicillin for a supposed pneumonia the report stating there was a 'slight increase in opacity in the right mid zone'. She returned home on Nov 6 quite well and with no clinical signs of pulmonary disease.

In another village three miles from the home of the child referred to above a small boy aged 2 years was seized with a similar pain at 6 a.m. on Nov 3, this continued, though lessening till 6 a.m. on Nov 4 after which he was well till 5 p.m. the next day, when the pain returned and continued till the late evening. He then slept well, and, apart from some guarding of his upper abdominal muscles which wore off in 24 hours, he remained well.

A child aged 4 years in the same village, who had been in contact with the small boy on Nov 1 commenced with pain at 4 p.m. on Nov 4 and it continued through the night but she was well on the two following days. The pain recurred on Nov 7 at 9 a.m., but ceased by 12 noon, since then she has been well.

When first seen these patients all showed obvious pain and anxiety, short and suddenly checked inspiration, longer expiration (not an expiratory grunt), rigid upper abdomen, slight fever, and a preference to sit up rather than lie down. Onset had been sudden, with a definite time stated by the respective parents. Remission of symptoms was more gradual and followed as suddenly as before by a further attack.

All three were, to my mind, cases of Bornholm disease, which I think may possibly be more common than is generally suspected, and they illustrate the advisability of refraining from the blunderbuss use of "sulpha" drugs in cases of apparent respiratory disorder, if only that more precise diagnosis may be made possible—I am, etc

### Fibrositis

SIR,—Before finally parting with a disease I thought I had suffered from for forty years may I put one question to those who have decided to abolish it? If, as they assert, all such troubles are due to articular lesions how comes it that the distressing pains radiating from the supposedly fibrotic nodules can be so definitely relieved by massage of them, as I know from grateful experience that they can?—I am, etc,

Eisted Sussex

ERNEST JONES

### Vegetable Marrow Poisoning

SIR,—The following case of poisoning by a vegetable marrow may be of interest to some of your readers.

A retired professional gardener planted a seed in the soil of his allotment and in due time three normal looking marrows were produced. The ground was clean and had not been manured previously, nor had any manure been used while the plant was growing. The first marrow was prepared in the normal way and served with meat and potatoes but the taste was so bitter that the man and his wife and daughter spit out their mouthfuls and discarded their helpings without swallowing either marrow or juice. The second marrow was quite normal in taste.

The third was prepared some time later and served with mince-meat, beans, and potatoes. The daughter and husband noticed that this was again bitter and discarded their helpings without swallowing marrow or juice, but the wife although discarding her helping of marrow, mixed the juice with the beans and potatoes and finished the meal. About five hours later she had a sudden attack of colicky abdominal pain followed by intense vomiting and diarrhoea. She was prostrated, and her symptoms lasted through the night. The attack then decreased in severity till the following evening, when she was well enough to get up. She has been well since then.

The man sought advice from the local health authority, and investigation failed to show evidence of extraneous infection of any kind. It was felt that the answer lay perhaps in the strain of the seed from which these marrows had grown. Samples of the last marrow were therefore sent to the nurseries

from which the seed had been obtained, but they could throw no light on the problem. A third sample was sent to the county agricultural education department, who asked the public analyst to analyse it. He has kindly allowed me to quote his report, which is as follows:

Some members of this family of plants are intensely bitter and are used medicinally for this purpose. Occasionally plants do revert and have this very bitter taste. The reason for this instability is obscure and does not appear to be due to soil conditions, as normal fruit and bitter fruit are intermingled. In a similar instance we have shown the bitter principle to be a glucoside. Many of the glucosides are intensely poisonous and would certainly give rise to the symptoms described, although the danger in this case is mitigated by the fact that the taste is so nauseating that it is unlikely anyone would eat any appreciable quantity. Bitter fruits are generally smaller and rougher in appearance compared with normal fruit."

All three marrows in this case appeared normal in size, shape, colour and consistency—I am, etc.,

### Medicine as a Planned Economy

SIR—Dr O L Wade (Oct 16, p 721) complains that far too much reliance is placed on laboratory tests in diagnosing illness. This may be true of the younger members of hospital staffs, but I do not think it is true of the senior members, who have the tests made to complete the picture, the jigsaw puzzle they strive to put together. The result of the test may prove to be the important piece they have been seeking. For my part as a pathologist I have always stressed the importance of clinical observation. The fault of the clinician is that he so often does not consult the pathologist about the most suitable test to be undertaken.

If there are too many unnecessary tests demanded by the consultant this is certainly not true of the general practitioner whose neglect of helpful pathological investigation is much to be regretted, even the simple tests Dr Wade lists are asked for far too seldom, to the disadvantage of both doctor and patient—I am, etc.,

### H 11 in Malignant Disease

SIR—The condemnation of H 11 (Oct 16, pp 701 and 716) is in my opinion much too sweeping. I have treated seven cases of malignant disease with H 11 and feel that the results justify further use of this extract.

The first case suffered from carcinoma of the cervix which had been treated with radium unsuccessfully and was in a pitiable condition with wasting and pain requiring frequent injections of morphine. Under H 11 the pain steadily improved, appetite returned, and a secondary palpable mass in the pelvis disappeared. She appears to have made a perfect recovery, and is now in excellent health.

The second case was a man with carcinoma of the mamma with multiple secondaries, including one in the humerus, causing gross oedema of the arm with severe pain. He improved for a time. The growth in the humerus became smaller and the oedema very much reduced. His relief was so great that he was indignant that he had not been given H 11 sooner. After three or four months the secondary growths began to increase rapidly, he developed severe anaemia and died a fortnight later. Although a fatal termination was prevented the relief of pain and the increased feeling of well-being amply justified the treatment. He also had been previously treated with radium.

The third case suffered from gastric carcinoma with secondaries elsewhere confirmed by laparotomy. Under H 11 his appetite improved, he gained some gain in weight, and he felt so much better that he decided to return to his business. But after a stormy interview with his business he had a stroke and died suddenly.

The fourth case is a man with an inoperable suprasellar tumour causing progressive loss of sight, severe headaches, and pain in one arm. Under H 11 and gradually the pain in his arm has disappeared. The headaches are now not severe enough to bother him, and his sight is slowly improving. Whatever the ultimate result of H 11 has proved well worth while for the relief.

The fifth case had epithelioma of the jaw with secondary glands elsewhere. In this case H 11 did not appear to have any effect. The sixth case had recurrent carcinoma of the breast after surgical removal. Here again no effect followed the use of H 11 and she died.

The seventh case had carcinoma of the cervix and rectum. The pelvis was full of growth, causing retention of urine, and nothing but flatus was being passed from the bowel when she came under my care. H 11 was immediately started, and in two weeks faeces began to be passed and the bladder began to act regularly. Catheterization has not been required since. The abdominal pain she was suffering has all gone, her appetite is moderate, she feels well, but she is not gaining weight and the outlook is very doubtful, but the relief given by H 11 has been great.

All the cases had been seen by experienced surgeons and radiologists, and the correctness of the diagnoses is above question. I feel that there is something in H 11 and regret that it is only in those cases in which surgery and irradiation have failed that one can feel justified in using it at present—I am, etc.,

### Delayed Diagnosis of Phthisis

SIR—It was with great interest that I read Dr Peter Stradling's analysis (Nov 6, p 832) on the delays which ensue in the diagnosis of phthisis. There are few chest physicians who will cavil with his general observations and recommendations. Most workers in this field agree that the manifestations of pulmonary tuberculosis are protean in character, and it would therefore be valuable to learn what precise criteria the author accepted as being suggestive symptoms (in all his cases) which should have reasonably commended themselves to the attention of the general practitioner. There may be a very real danger otherwise that his analysis scarcely does justice to the harassed and overworked practitioner. Again, it is difficult to appreciate what Dr Stradling means when he states, "The general practitioner in particular does not at present fully utilize his unique opportunities of raising the Tuberculosis Service from its present mediocrity (my italics) to the highly efficient organization that it might and should be." This is a very serious charge that is being levelled against the entire service, and it would be revealing to learn the source and authorship of this information. Is this to be taken as the overall picture of the metropolis, of Willesden or is this the fruit of Dr Stradling's experience of the bulk of chest clinics from Land's End to John o' Groats?

Finally, I must take the author to task when he misinterprets or misquotes a paper of mine which appeared in an issue of this *Journal* (1943, 1, 283). In this he states that my findings and his were not strictly comparable, as his "refer to a chest clinic, Mann's to a sanatorium." In fact, I gave no indication that such was the case, and they, like his own, were extracted from several chest clinics in the West Riding of Yorkshire. However, the two groups of statistics are for an entirely different reason in no sense comparable. Whereas Dr Stradling's are those of a clinic in the heart of the metropolis mine were those of an extensive rural area where indifferent transport facilities and wartime difficulties were no doubt contributory factors in giving a much longer hiatus before the general practitioner was consulted—I am, etc.,

BERTRAM MANN

### Self-administered Pneumothorax Refills

SIR—Dr Philip Ellman's letter (Oct 16 p 723) reminds me that in 1910 my old friend Claude Lillingston gave himself a refill on his arrival in England from Norway. This was the first that had ever been given in England. A week or two later I gave him his next refill, at which time we put together the apparatus named after us.

I am also reminded of a one-time patient of mine whose APT I started in November, 1913, when he was 28. He was a TB-positive case who had been originally slightly ill and in the Mundesley Sanatorium when 21. In 1913 he had signs over the upper half of the left lung and did not improve appreciably after four months conservative treatment. Recovery proceeded quickly after the APT. I did not see him again for ten years, when he astonished me by telling me that he was continuing to keep his APT going by self-administered rather large refills at five-weekly intervals. He was keeping perfectly fit, following his profession, that of an artist and had not visited a doctor.

In 1934 he wrote me that he was keeping very well and still continuing refills—self-administered—about 250 ml every five weeks. These he continued for several more years maintaining excellent health. But later his health broke down I believe badly and from pulmonary tuberculosis (querv in the other lung). I fancy the patient is now dead. The A.P. had been kept up for not less than 25 years. In 1924, when I made a sketch from a screening I did, he had a well collapsed left lung without displacement of the heart but with some adhesions low down laterally.

One or two more of my ex-patients used to give themselves self-administered refills, and one of these at least was not a doctor. But their cases were not so exceptional as the two I have mentioned above—I am, etc.,

### Breath Sounds in Spontaneous Pneumothorax

SIR,—Recently, while preparing a lecture on spontaneous pneumothorax, I was struck by the inadequacy and inaccuracy of the descriptions of the stethoscopic findings in this condition in the textbooks I had to hand. I think it is important that the attention of students be drawn to these omissions and inexactitudes, because the sound caused by air escaping from the punctured lung into a pneumothorax cavity is one of the most characteristic and easily memorized sounds heard on auscultation, and it is a sound which often enables a confident diagnosis to be made. It is correct to say that this sound has a metallic or amphoric quality. It begins later than the inspiratory breath sound is often interrupted or cog wheel in type and may be heard during inspiration and expiration. It can be so distant and faint that it can easily be overlooked. A similar sound can be produced by sucking air rapidly from an open pneumothorax through an aspiration needle. In a closed pneumothorax this sound is, of course, not heard.

Textbooks describe amphoric breath sounds in a pneumothorax. Amphoric breathing is never heard in a pneumothorax. The sound caused by air escaping into the pleural cavity is not a true breath sound, whereas breath sounds in a closed pneumothorax if audible, have not an amphoric quality.

Every spontaneous pneumothorax is open at the onset—how long it remains open varies from hours to months, but there is always a stage when the escaping air can be heard if the patient is examined early enough. It is sometimes possible to diagnose a pneumothorax by auscultation in a case where it has never been suspected—e.g., in a case without pain and dyspnoea and without obvious cardiac displacement—I am, etc.

R FAWCETT STRONGE

### Resuscitation by Rocking

SIR,—We were interested in the article by Dr F C Eve and the late Dr N C Forsyth (Sept 18, p 554) and the reply by Dr W N Leak (Oct 30, p 797) regarding the resuscitation of the asphyxiated newborn. For many years we have given nikethamide intracardially to the newborn babe which does not breathe. We use one ampoule of 17 ml "coramine" giving half into the left ventricle and the other half intramuscularly. The dose is split in this way because we find that the whole 17 ml given into the heart causes severe spasm and rigidity of all muscles including those of respiration and thereby defeats its own object.

If the baby does not breathe at once we proceed to mouth-to-mouth insufflation through a layer of gauze. An important practical point is to have a 2-ml hypodermic syringe and needle ampoule and file, spirit and swab, ready before the birth of every baby and to make these a routine part of the immediate pre-natal preparations.

We feel that if these measures fail Dr Eve's mechanical methods should be used but that the latter should not precede and should not replace the former. Nikethamide and insufflation can be used immediately they involve no loss of time, and their effect is almost instantaneous, whereas the mechanical methods do need time. Needless to say nikethamide and insufflation must be used before the heart stops beating—I am, etc.,

### Post-gastrectomy Syndrome

SIR—Your annotation (Sept 11 p 524) and articles by others on this subject in particular that by Dr W T Irvine (p 514) are of considerable interest and importance. The syndrome is a distressing post-operative complication of what otherwise is a very successful surgical procedure. My own observations based on an experience of thirteen years of the treatment of peptic ulcer and neoplasm of the stomach by partial gastrectomy may be of value.

I have seen a number of cases of the syndrome all presenting similar symptoms varying only in degree. Fullness and discomfort after food, generally accompanied by dizziness, sweating and a feeling of nausea, are the most common complaints. It is by no means always caused by the taking of a bulky meal but can follow a modest intake of food in many cases. Vomiting, when it occurs is of two types—an early-morning regurgitation of almost pure bile which I believe to be due to the loss of the pyloric sphincter control, and vomiting between meals not of actual food but of bile strained froth.

From a study of my cases certain facts have become apparent:

- 1 The syndrome appears to be becoming more common. I do not recollect seeing any cases in the follow-up clinic of the late Mr Cecil Toll prior to the second world war.
- 2 I have never seen it after gastrectomy for carcinoma.
- 3 It is less common after gastrectomy for gastric ulcer.
- 4 It is by no means so common in the older age group of patients—beyond the age of 45.
- 5 It does not tend to occur while a patient is in hospital, often not appearing until a week or two or even longer after discharge.
- 6 It is most common after gastrectomy for duodenal ulcer in younger male patients.
- 7 The type of gastrectomy performed would seem to be of little importance, and I have not seen it as a complication in my very small series of successful total gastrectomies.
- 8 The majority of the patients in my series were of the introspective type given to excessive worry, and those who have been passed over to my psychiatric colleagues for treatment were said to possess an "inadequate personality".
- 9 Not a few have responded to ordinary reassurance and sedatives.
- 10 It would appear to be a self-limiting condition. Most cases have cleared up in a matter of six months after operation whether treated or not. They themselves and what remained of their stomachs appear to have become adjusted to the altered conditions.
- 11 The more intractable cases have responded well to a course of narcosis and psychotherapy.

My deductions from the above make me believe that there is a strong psychological element as a background to the syndrome (duodenal ulcer itself is held to be a psychosomatic disorder). Coupled with the altered mechanics of the upper intestinal tract brought about by operation, hypoglycaemia certainly is present, but would now appear to be of only secondary importance as a causal factor. Neither can overdistension be blamed, as it is so easily avoided by eating "little and often" rather than taking three bulky meals. There is no truth in the so-called dumping theory, if by such is meant the logging of food in the proximal loop. X-rays following a barium meal have never revealed such to be the case in my experience. The onset of the syndrome usually coincides with the patient's discharge, when he has to go back to face the world and its vicissitudes once again—that is, when he is removed from the shelter of the hospital and medical attention. The worst thing possible after gastrectomy is to allow the patient to go on thinking that he is still an invalid. All my post-gastrectomy cases are encouraged to return to work as soon as possible, to forget that they ever had indigestion, to eat what they like and to enjoy life, with an injunction to observe all the virtues and in moderation some of the vices.

As to the treatment of the syndrome itself, reassurance and suitable sedation are oftentimes successful, together with adjustment of the intake of food and of meal times until what remains of the stomach and the proximal jejunum can adequately compensate for the altered conditions. The most intractable cases have been submitted to narcosis and psychotherapy with great success by my colleague, Dr A A Martin of the Bucks County Mental Hospital, and we hope to publish a series of these cases in the not far-distant future. I have no personal experience of vagotomy, as I have not yet adopted it as a therapeutic procedure in the treatment of ulcer. Finally, Dr F Lindsay Dickson's letter (Oct 23 p 759) in which he enumerates his unfortunate personal experience of

he syndrome and his comments thereon, coincides with my own findings. I trust that his complacency since July 5 (which I, unfortunately, am unable to share) will have completed his cure—I am, etc.,

Arystury Bucks

RALPH H GARDINER

### Use and Abuse of Tonsillectomy

SIR—The whole question of the success or otherwise of the operation for the removal of enlarged tonsils and adenoids depends on a proper selection of cases. After a large number of years as a general practitioner and assistant medical officer of schools I came to the following conclusions

1 It is one of the most successful operations when performed in suitable cases

2 It is often performed in unsuitable cases

3 The habit of bracketing tonsils and adenoids together is a mistake. Enlarged adenoids are infinitely more often the cause of trouble than enlarged tonsils, because they quickly obstruct nasal breathing and give rise to mouth breathing. Enlarged tonsils alone very seldom do this.

4 Tonsils should not be removed just because they are enlarged or because purulent looking material can be expressed from them. Tonsillectomy should only be performed when there is a history of recurrent attacks of tonsillitis with persistent enlargement of the tonsillar glands of the neck.

5 Adenoids, however, should be removed if causing slight nasal obstruction, deafness, or earache, and should always be followed by deep-breathing exercises through the nose to re-establish nasal breathing. If nasal breathing is not re-established the condition will recur.

I believe that in children the tonsils are part of the mechanism for the manufacture of the antibodies of various infections, particularly streptococcal ones, and should be preserved if carrying out those functions properly. Persistent enlargement of the tonsillar glands is evidence that they have failed and have become a permanent source of infection and should therefore be removed. Selection of cases on the above lines would, I believe, give better results and go a long way to relieve the present shortage of beds—I am, etc.,

St Mawes Cornwall

N C PENROSE

### POINTS FROM LETTERS

#### Partridge Bone in Anal Canal

LIEUT J S HAPPEL, R A M C (B A O R), writes. The following case may be of interest and must be rather unusual. The patient was a stout woman, aged 37, who complained of excruciating pain in the anus. Pain dated from three hours earlier, when she had defaecated—a normal motion. Inspection of the anus revealed several small thrombosed external haemorrhoids. The anal sphincter was in extreme spasm, and a finger could not be introduced into the rectum. A presumptive diagnosis of strangulated internal haemorrhoid was made. 16 mg morphine given, and heat applied to the rectum. Seven eight hours later spasm had subsided considerably, and digital examination of the rectum was carried out. A thin sliver of bone two inches (51 cm) long was found lying obliquely in the rectum with its proximal end embedded fairly firmly in the posterior wall of the anal canal at the junction of the superficial and deep pouches of the sphincter. It was removed without much difficulty. I was surprised that the patient had eaten partridge 48 hours before. It is rather astonishing that many feet of bowel should be traversed successfully only for a hold up to take place in the last inch and a half.

#### Breast-feeding

DORIS S HALL (Waimere Kent) writes. Your correspondent Dr F. A. Bidder (Nov 6, p 838) ends her plea for breast feeding with the statement that to persevere with it is 'depriving the baby of its health'. This is an admirable sentiment, but is it true? I am finding that fewer and fewer mothers are now satisfied with breast feeds, yet their children remain healthy. With more than twenty five years experience and four children of my own all bottle-fed, I cannot determine that breast feeding has any deterrent effect whatsoever. On the other hand there is a bad history of breast-feeding with the children of my own. To persevere again with the breast is asking for trouble, and child I am of course open to the view that modern evidence be available to the contrary. I will concede the point that on general grounds in the modern world it may be a good thing to make breast feeding harder for the mother.

## Obituary

JOSEPH BLOMFIELD, OBE, MD

Joseph Blomfield, consulting anaesthetist to St George's Hospital, died in the West Middlesex Hospital, Isleworth, on Nov 9, the hospital at which he did his E M S work during the war. He was born in London on March 1, 1870, and was educated at University College School and Cambridge University. He entered St George's Hospital in 1891, and graduated MB, BCh in 1894, he proceeded MD in 1897. After minor appointments early in his medical career he took up anaesthetics as a specialty, but it was some years before he finally settled down at St George's. For periods he was anaesthetist to many hospitals, including the Metropolitan, St Mary's, St John and St Elizabeth, the National Dental, and the Grosvenor Hospital for Women and Children. He was senior anaesthetist at St George's from 1906 until he retired in 1931.

In 1900 he was elected to the select, but small, Society of Anaesthetists, and of this body he became senior secretary in 1905. He was one of the outstanding members of the Society, and it was to a great degree his influence which induced the Society against the strong opposition of many of the older members to form a Section of Anaesthetics at the Royal Society of Medicine. This argument split the old Society of Anaesthetists into two almost equal parts: the members of the Society who were in favour of the proposal became the original members of the Section. Blomfield was one of these, and before many years had passed he became president. He held this office with dignity, being as excellent a president as he always was a chairman of the many societies and committees to which he belonged.

He was a founder of the Association of Anaesthetists, was the first vice-president and the second president, and for a short time after the tragic death of Howard Jones, who was the honorary secretary, he undertook secretarial duties. He was chairman of the Anaesthetists Committee of the Medical Research Council, for which he did yeoman service in dealing with the innumerable new drugs. In the first world war he held a commission in the R A M C and was attached to St George's Hospital, which became part of one of the London general hospitals. This entailed very heavy work, but Blomfield found time to give his services at many officers' hospitals, the chief of which was the King Edward VII Hospital, Grosvenor Gardens, where Sister Agnes, a well-known Edwardian figure, was in charge, with whom he became great friends. He was given the OBE in 1919.

For many years Blomfield was a pioneer in anaesthesia, and no anaesthetic group or society was complete without his name. In his younger days he was an able and fluent speaker. He was popular with those colleagues who knew him well enough to appreciate his worth, but he never pushed himself in any way and he appeared rather retiring and almost shy to those who did not understand him. As an anaesthetist he was one of the old school. He was conservative in outlook and inclined to regard some of the modern innovations as but passing phases, for he had seen many new methods started, forgotten, and then again brought forward as something new.

Some of his best work was done when 'avertin' was first introduced into this country, he was chairman of the Anaesthetic Committee of the Medical Research Council at the time. His work at St George's did much to popularize his method of rectal anaesthesia, which soon became a fashion, if not a craze. Blomfield was the first to point out the limitations of the method and also the danger of using morphine in conjunction with avertin.

Blomfield and Fry

He was a good writer and will be best remembered as such for years Blomfield was editor of the *British Journal of Anaesthesia* and of the section of anaesthetics in the *Medical Annual*. He was author of a popular book entitled *Anaesthetics* which ran through many editions. In 1922 he published another book *Anaesthetics in Practice and Theory*. He wrote many articles in medical journals and in surgical textbooks. He was also author of a history of St George's Hospital written to commemorate the bicentenary of the hospital.

He was a most regular attendant at the university cricket match at Lord's, and nothing would prevent his annual appearance at this function. In 1945 he was very seriously ill, and, although he made a good recovery, he never regained his full vigour. He still attended many of the meetings of societies, and his presence among the senior members will be much missed. In 1948 he was elected a Fellow of the Faculty of Anaesthetics, Royal College of Surgeons. Without doubt he was a pioneer in anaesthesia, and he has left his mark upon the history and literature of that branch of medicine.—Z M

#### J P HELLIWELL, CBE, MRCS, LDS

John Percival Helliwell, consulting dental surgeon to the London County Council and formerly Director Army Dental Service, died on Nov 7 at the age of 64. He received his professional education at Manchester University and at St Mary's Hospital, London, and he qualified as a dental surgeon in 1908. In 1910 he was one of the three civilian dentists selected by the War Office to look after the teeth of soldiers serving in India. This was the beginning of the Army Dental Service. He was commissioned in the RAMC in 1915 when Army dental officers were first admitted to the Corps. He became Inspector of Dental Services at the War Office in 1918, and when the Army Dental Corps was established in 1921 he was chosen to organize it. He believed that dentistry was a branch of medicine and feeling the necessity for a medical qualification he qualified in 1926 at the age of 42. In the same year he was appointed Assistant Director-General, Army Medical Services, with the rank of colonel. He was appointed the first director of the Army Dental Corps in 1935 and was promoted to the rank of major general—the first dental surgeon to attain this rank. He retired from the Army in 1936 and became consulting dental surgeon to the London County Council, which was then reorganizing its hospital and school dental services. He was an able administrator and organized with great success both Army and civilian dental services. He was chairman of the Army advisory committee on maxillo facial injuries and a member of the Interdepartmental Committee on Dentistry. He was made a CBE in 1919 and was Colonel Commandant of the Army Dental Corps from 1932 to 1947. He is survived by his widow and a son and daughter.

W R Y writes. With the death of Major General Helliwell the dental profession has lost one of its most outstanding personalities, and many of his colleagues have lost a true and valued friend. Throughout his professional career he strove consistently for those high ideals which would increase the dignity and appreciation of the dental profession, and the many advances in Service and civil dental organization for which he was responsible will remain a lasting tribute to his memory and to his sound judgment. He expressed pronounced and well-considered views to which he held courageously, sometimes in the face of considerable opposition and his opponents would readily concede the sincerity and selflessness of his aims and ideals. No one who knew him intimately could escape the kindly influence of his charming and gracious personality, and to many he endeared himself in a measure not often given to those who hold high and responsible office. It was a matter of great concern to his friends that his last two years were clouded with ill health but his strength of character and sterling qualities were exemplified in the fortitude and courage with which he withstood his affliction.

Dr EDWARD PIRCY HUGHES DUDLEY died suddenly on Oct 28 at his home at Caxton Cambridgeshire at the age of 74. Dr Dudley who was a student at St Bartholomew's Hospital, qualified in 1904 and joined the late Dr White in partnership at Caxton in 1908. For 40 years he carried on a scattered rural practice conducting his own family medical clubs with a simple form of administration suited to his needs and to those of his

patients who were chiefly farmers and their workers. Dr Dudley had been a keen member of the BMA since 1908 and he was chairman of the Cambridge and Huntingdon Division in 1924-5. He was also for some time a member of the Cambridge Local Medical and Panel Committee. He is survived by his widow and one son and one daughter.

L B S writes. By the tragic death of Dr E P H Dudley the countryside has lost more than a trusted doctor and familiar figure of the Cambridgeshire by ways. It is as though one of the last remaining strongholds against the mechanized advance of bureaucratic medicine has fallen. Dr Dudley enjoyed a high reputation in the county mansions, but it was in the cottage that he was seen at his best. A somewhat diffident manner disguised an inflexible resolution, a profound knowledge of the human animal was combined with a boyish curiosity as to the new, and his ear contained in ever increasing profusion the latest therapeutic agents and instruments of minor surgery. His alacrity to seek assistance was perhaps partly due to a skill in prognosis which amounted almost to instinct and any little service was repaid a hundredfold. He was kindness itself and never spared himself, carrying on his arduous practice with great courage throughout the war years, and turning when it was over, to face the appointed day for the National Health Service Act with full knowledge of what it would mean to him and all he represented.

J M T writes. Dr Dudley succeeded his father in law, a bearded majestic figure, who did his rounds on horseback and often combined them with riding to hounds. The motor-cycle and car did little to alter the work except to increase it greatly especially was this so in wartime. The area of the practice is immense, and it was quite usual for the doctor and his assistant each to do nearly a hundred miles in the day. The writer spent two happy years there and learnt to admire the courage and generosity of a man who, no longer young, always went out no matter what the weather. Even deep snowdrifts would not deter him. Every day was a field day. There was first an unhurried, leisurely preparation of medicines and discussion of cases in the surgery and dispensary, with its open fireplace, the old tap room of the Crown House, Caxton, where Dick Turpin and his mare Black Bess once lodged. At most three or four patients would attend with forms to be filled in or with requests for visits. Then everything would be packed into the cars, the great doors of the yard would be opened, and off we went perhaps not to return until 10 at night. Dr Dudley had a deep sense of the worth of his calling and an amused and shrewd perception of the peculiar social position of the medical practitioner in the country. His greatest pleasure was in good natured co-operation with his colleagues, and it was to his regret if ever a spirit of rivalry and competition came in to spoil such good relationships. He belonged to a generous age and knew it.

## Medico-Legal

### FATAL DERMATITIS FROM PYELECTAN

[FROM OUR MEDICO LEGAL CORRESPONDENT]

A married woman of 47 was admitted to the Minehead and West Somerset Hospital for investigation. She was given an injection of "pyelectan," and developed acute dermatitis and toxæmia from which she died in about two weeks. The pathologist who conducted the necropsy, Dr Crichton MacGaffey, said that he had found no undoubted evidence of tuberculosis (the patient had recently been treated in a sanatorium), he took it that she had been discharged as cured and it was a very good cure. The cause of death was first subacute haemorrhagic glomerular nephritis and secondly dermatitis venenata due to the dye. The point was raised that the injection had been given before the report on the urine had come back from the laboratory at Exeter, and he was asked whether it had been reasonable to inject pylectan before the result of the analysis was known. He answered that this was perhaps a matter of opinion. He himself would have suggested that the microscopic findings should be viewed first of all. There was no urgent necessity to give the injection but the hospital staff were out to do a thorough job. They might have been short of time or bed space and have wanted to get it done, but he thought it would have been wiser "to have done the thing one stage at a time. There was no antidote to the dermatitis and it was a very unusual thing

course of action  
against chilblains ...

Three or four months may yet pass before the chilblain season is at its height. But active anticipation of the wintry weather can make the future a great deal brighter for those inveterate chilblain cases. Started now, a daily routine of four Ostocalcium Tablets will make an essential contribution towards the healthy capillary circulation so vital in withstanding the cold. Ostocalcium exerts a controlling influence on the permeability of the capillaries, preventing the exudation of fluid into the tissues that causes the characteristic swelling and inflammation. And the Ostocalcium formula takes full account of the need for vitamin D in calcium therapy: each tablet containing 500 i.u. of the vitamin with 125 milligrams of calcium.

# MULTIS TERRIBILIS CAVETO MULTOS (AUSONIUS)

Those that are a cause of fear to many should themselves avoid crowds. In Rome, do as the Romans do. But in modern times crowds are as difficult to avoid as the virus of the common cold. Endrine nasal compound provides a simple method of relieving coryza and catarrh. It contains ephedrine which shrinks the inflamed mucosa whilst the menthol brings soothing relief to the inflamed membranes. Free breathing becomes possible and infection is prevented.

## ENDRINE Nasal Compound

Formula: ephedrine 0.5% w/v, menthol 0.5% w/v, camphor 0.5% w/v, eucalyptol 0.5% w/v, clemastine fumarate 0.5% w/v, p-menthane-1-thiol 0.5% w/v.

# A new approach to the relief of pain

TETRAETHYLAMMONIUM salts were found in 1945 to block the transmission of nerve impulses through the autonomic ganglia, and they have been employed diagnostically in selecting patients for sympathectomy suffering from peripheral vascular disease.

Tetraethylammonium Bromide may be used therapeutically to give relief from pain in peripheral vascular disorders, causalgia and post-herpetic neuralgia.

Injection of T.E.A.B.-Boots. Supplied as a 10 per cent solution for intravenous or intramuscular injection. —Boxes of 12 x 1 c.c. and 12 x 5 c.c. ampoules.

## These remarkable radiographs show WHY INTALOK ELIMINATES BED-FATIGUE

*Multitudes of fine springs provide medically  
correct support without flattening  
the fleshy parts of the body*

*The patient on the Intalok mattress in the radiograph below is a normal 11 stone man. The area shown is the lumbo sacral region.*

The two radiographs reproduced on this page illustrate clearly the finely sprung area of support of an Intalok hospital mattress and show why patients placed upon Intalok remain noticeably free from symptoms of bed fatigue even when confined to bed for long periods. Fig 1 is a section of the mattress uncompressed. Note the method of the springing. Hundreds of fine gauge springs are linked together throughout their lengths to form a "squab" a finely sprung unit which combines to receive weight. What this scientific springing does under the weight of the patient is shown in Fig 2. Note how every spring shares some part of the load. The compression of the springs vary exactly with the shape of the body. There is no excess pressure or resistance at any point, no flattening of the fleshy parts of the body to cause soreness or irritation. Yet support is firm anatomically correct. The spine is held in its naturally straight position. The result is exceptional comfort and no fatigue. Doctors, matrons and other hospital authorities have noticed that patients relax as soon as they are placed on Intalok. Patients stay relaxed enjoying more sleep and when awake a greater degree of restful quiet. There is a strong case for Intalok mattresses in hospitals.

## A new applicator for Volpar paste

A specially designed Volpar Applicator is now available for patients overseas where Volpar Paste is used instead of Volpar Gels and with equally satisfactory results.

Volpar preparations have been prescribed and used on an increasing scale throughout a decade and abundant evidence of their efficacy, acceptability and innocuousness has been produced.

Descriptive literature is available, on request

# BELLADENAL

**Antispasmodic .. Anticonvulsive  
:: Sedative ::**

**B**ELLADENAL combines the central sedative action of phenobarbitone with the peripheral antispasmodic action of the total laevorotatory alkaloids (Bellaloline) of *Belladonna leaves*. Bellaloline is only half as toxic as atropine in doses which are therapeutically equivalent in their effect on the parasympathetic.

Each tablet of Belladrenal contains

Bellaloline	0.25 mg
Phenobarbitone	0.05 Gm

The components of Belladrenal act synergistically with each other so that a powerful antispasmodic and sedative effect is obtained with comparatively small doses.

to have happened. He did not think it would happen more easily in a person who had had tuberculosis than in one who had not.

The coroner said he thought the hospital authorities had been acting reasonably in the sense that they wanted to make a thorough investigation. The case had been quite rightly reported to him. He recorded a formal verdict of death by misadventure.

## Medical Notes in Parliament

### Artificial Limbs

Mr MARQUAND told Mr Morley on Nov 9 that a research unit at Rochampton worked under the direction of the Standing Advisory Committee on Artificial Limbs, of which Sir Charles Darwin was chairman. The second report of the committee, issued in April this year, showed the lines on which research is developing. He circulated in the official report a note on the practical results and the improvements to be expected in the near future. This note ran: *Research work on artificial limbs*—(1) A number of new arm appliances have been added to the existing list and others are being re-designed and improved. (2) A new artificial arm of improved design has been developed. Six trial orders have been placed, and should these prove satisfactory in all respects the arm will go into general production. (3) A new method of suspension of an artificial leg by suction socket has been developed and is under trial by patients, the trials are most encouraging. (4) A socket of new design for above-knee amputation has been produced and is under trial by over 100 patients. (5) Two new mechanical hands have been submitted by the contractors to the Ministry and are under trial. (6) An apparatus has been designed and is under experimental test for measuring comparatively the thrust which walking imposes on both the artificial and the sound limb. By means of this apparatus it is hoped that much valuable information will be obtained. (7) Work is proceeding on the improvement of crutches, new ideas for which have recently been received by the research department.

### Pneumoconiosis

Mr JAMES GRIFFITHS told Dr Barnett Stross on Nov 9 that in 1947, 48 miners in North Staffordshire were certified as suffering from pneumoconiosis as compared with 61 in 1946 and 99 in 1945. He said that although these figures showed a steady reduction it was too early to draw any conclusions from them. The figures include cases of silicosis, as separate figures for silicosis were not available.

### Trial of German Field-Marschals

Asked by Mr WARD on Nov 9 why his Department's doctors did not accompany the Home Office doctors when they examined the German field-marschals in April, 1948, Mr SHINWELL said it had been considered that the two examinations should be independent. The Army medical board expressed agreement with the findings of the Home Office doctors on the question of fitness to stand trial.

Mr NICHOLSON on the same date inquired if the medical officers who visited the German field marshals in January had any instructions other than to determine whether trial would adversely affect their health.

Mr SHINWELL replied that the Army medical board was instructed to submit a general report on the health of the officers and an opinion on whether it would adversely affect their health to be tried as war criminals. The board gave a full medical report on the condition of the officers and stated that in its opinion it would adversely affect their health to be tried as war criminals. Later, in April, after the officers had been independently examined by the Home Office medical officers, the Army medical board agreed with the Home Office medical officers that three of the accused were fit to stand trial but that the fourth was not.

### Medicines for Private Patients

Sir WAYNE WAKEFIELD on Nov 11 asked the Minister of Health, in view of his refusal to permit private patients to obtain pharmaceutical services free of charge, to withdraw the pamphlet 'The New National Health Service,' in which it was stated that any person could use the whole or any part of the Service.

Mr BEVAN was unwilling to do this. He said people were perfectly free to use any part of the Service, but there must be a limit to the extent to which parts could be subdivided. He would not feel justified in supplying medicines or appliances ordered by doctors who were not taking part in the Service and were under no obligation to observe its rules.

### Hearing-aids

Mr BEVAN announced on Nov 11 that the following Hearing-Aid Distribution Centres were in operation: Sunderland Royal Infirmary, Cumberland Infirmary, Carlisle, Bradford Royal Ear and Eye Hospital, Royal Sheffield Hospital, Nottingham General Hospital, Norfolk and Norwich Hospital, Royal National Throat, Nose and Ear Hospital, London, King's College Hospital, Metropolitan Ear, Nose and Throat Hospital, London, Radcliffe Infirmary, Oxford, Northampton General Hospital, Prince of Wales Hospital, Plymouth, Bristol Royal Infirmary, Birmingham and Midland Ear and Throat Hospital, North Staffs Royal Infirmary, Stoke-on-Trent, Manchester Hospital for Consumption and Diseases of the Throat and Chest, Queen Victoria Royal Infirmary, Preston, Liverpool Eye, Ear and Throat Infirmary. Additional centres would open in the next few weeks at Hull Royal Infirmary, Addenbrooke's, Cambridge, London Hospital, Kent and Canterbury Hospital, Canterbury Royal South Hants Hospital, Southampton, Cardiff Royal Infirmary, War Memorial Hospital, Wrexham. There were also a much larger number of hospitals where patients might be examined by otologists before obtaining an aid from one of the above distribution centres.

### Claims for Compensation

Sir ERNEST GRAHAM-LITTLE on Nov 11 asked whether Mr Bevan knew of the uncertainty among general practitioners about the amount of compensation to which each practitioner would be entitled under the National Health Service Act, 1946, and, as the list of applications had been closed, whether he would give the total number of practitioners between whom the global sum available would be divided and the total of their claims.

Mr BEVAN answered that under the National Health Service (Medical Practice Compensation) Regulations, 1948, claims were to be submitted by Oct 31, but late claims if there were satisfactory reasons for the delay, could be admitted to April 30, 1949. A final determination of the total amount of compensation would not therefore be possible until after that date. Up to date 13,661 claims had been received from medical practitioners in England and Wales.

### School Dentists

Mr GEORGE TOMLINSON stated on Nov 11 that a good many school dentists were resigning to set up in practice under the National Health Service. Recruits were not coming forward to fill their place. In consultation with the Minister of Health he was considering the salaries of full-time dentists in the employment of local authorities.

**Pensions**—The disability pension payable to a pensioner who suffers from a tropical disease will not necessarily be affected by the fact that pathological tests become negative, since pension is assessed on loss of functional capacity, which may persist after the negative test.

**Clean Food**—On Nov 8 Mr HARRISON asked the Minister of Food, whether in view of recent prosecutions for preparing food in filthy conditions, he would review his regulations and their enforcement in food preparation depots. Mr STRACHEY replied that the conditions under which food was prepared for sale for human consumption were governed by the Food and Drugs Act, 1938 which was enforced by local authorities. Recent cases had not disclosed defects in this Act, but they underlined the importance of rigorous enforcement. Officers of the Ministry of Food had instructions to co-operate to the fullest extent with officers of the local authorities with a view to bringing to justice those who for personal gain disregard the public welfare in this way.

**Partnerships**—Mr BEVAN received on Nov 8 the Report of the Legal Committee on Medical Partnerships and is considering it.

**Unsplinterable Lenses**—Mr BEVAN is considering whether it is possible to supply unsplinterable lenses under the National Health Service.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

On Oct 30 the degree of M.D. was conferred on \*R. A. D. Crawford, J. N. Milnes, J. S. Heller, and P. D. Sammin.

\*By proxy.

### UNIVERSITY OF GLASGOW

On Nov 6 the degree of M.D. was conferred on T. McEwan and the degree of Ph.D. on I. C. Michaelson, F.R.F.P.S., D.O.M.S.

### UNIVERSITY OF ABERDEEN

At a graduation ceremony held on Oct 27 the degree of M.D. (with commendation) was conferred on H. McL. Raffan.

### UNIVERSITY OF LONDON

Dr J. W. Trevan, F.R.S., will deliver two lectures on Statistics from the Standpoint of a Pharmacologist in the Physiology Theatre of University College, Gower Street, W.C., on Wednesdays, Dec 1 and 8 at 5.15 p.m. The lectures are open to members of the public without fee or ticket.

The University Court has elected Sir Henry Dale as its Deputy Chairman for 1948-9.

Dr Charles Reid has resigned the post of Reader in Physiology at London Hospital Medical College, from Sept 30.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

Mr A. Dickson Wright will deliver the Dr John Burns Lecture in the Hall of the Faculty (242 St Vincent Street, Glasgow) on Wednesday, Nov 24 at 5 p.m. His subject is "Vascular Surgery." All medical practitioners are invited to attend the lecture.

## EPIDEMIOLOGICAL NOTES

### Discussion of Table

In England and Wales the increase of 908 in the notifications of measles was the only rise in the incidence of infectious diseases. There were falls in the incidence of whooping cough 103, dysentery 31 and diphtheria 24.

The largest rises in the notifications of measles were Lancashire 221, Essex 114, Monmouthshire 107, Derbyshire 104 and Southampton 90; the largest fall was 66 in Lincolnshire. Only small changes occurred in the returns for whooping-cough, the largest were a decrease of 43 in Cornwall and an increase of 32 in Yorkshire West Riding. No large variations were recorded in the local trends of scarlet fever. The largest fluctuations in the returns of diphtheria were a decrease of 10 in Lancashire and a rise of 8 in both London and Essex.

Three more cases of typhoid were notified from the outbreak in Shropshire, Oswestry R.D. The only large return for dysentery was 20 in Lancashire. A fall of 10 in the total notifications of poliomyelitis resulted in the smallest number of notifications since the middle of August. The largest returns of poliomyelitis were London 9, Lancashire 5, Kent 4, Norfolk 4, Yorkshire West Riding 4, and Glamorganshire 4.

In Scotland decreases occurred in the notifications of measles 53 and whooping cough 20 while rises were reported for scarlet fever 43 and diphtheria 24. A small rise in the incidence of diphtheria occurred throughout the country. The increase in cases of scarlet fever was confined to the western area. In Edinburgh a rise of 12 was reported in the number of notifications of dysentery but elsewhere in the country a slight fall was recorded. An outbreak of paratyphoid fever has been reported from the city of Aberdeen, and up to Nov 9 there were 11 cases (3 in one family). The origin of the outbreak is at present unknown.

In Eire rises were recorded for measles 90, diarrhoea and enteritis 37 and whooping cough 14; a fall was reported for scarlet fever 20. The notifications of measles in Loughis Athy No. 2 R.D. rose from 15 to 71. In Dublin C.B. the notifications of diarrhoea and enteritis increased from 17 to 47.

In Northern Ireland a decrease of 59 in the number of cases of measles notified in Belfast C.B. was the chief feature of the returns.

### Week Ending November 6

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1471, whooping-cough 2240, diphtheria 171, measles 6177, acute pneumonia 496, cerebrospinal fever 21, acute poliomyelitis 73, dysentery 55, paratyphoid 3 and typhoid 4.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct 30.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

Smallpox Deaths	—	—	—	—	—	—	—	—	—	—
Typhoid fever Deaths	10	—	1	1	—	4	—	—	11	—
Typhus fever Deaths	—	—	—	—	—	—	—	—	—	—
Whooping-cough* Deaths	2060	127	75	66	16	1037	59	41	45	6
Deaths (0-1 year) Infant mortality rate (per 1000 live births)	259	30	43	13	13	336	38	64	29	22
Deaths (excluding still births) Annual death rate (per 1000 persons living)	4491	723	547	166	118	4415	739	590	172	118
Live births Annual rate per 1000 persons living	7419	1184	870	406	226	7626	1240	954	364	209
Stillbirths Rate per 1000 total births (including stillborn)	176	27	36	—	—	203	34	35	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales (London administrative county) will no longer be published.

‡ Includes primary form for England and Wales (London administrative county) and Northern Ireland.

§ The number of deaths from poliomyelitis and poliomyelitis for England and Wales (London administrative county) are combined.

|| Includes puerperal fever for England and Wales and Eire.

# Medical News

## Birth of a Prince

A son was born to Princess Elizabeth at Buckingham Palace on Nov 14, and was attended by the following medical men: Sir William Gilliat, Mr John H Peel, Dr V F Hall, Sir John Weir.

Sir William Gilliat, President of the Royal College of Obstetricians and Gynaecologists, received his medical training at the Middlesex Hospital, qualifying in 1908. He obtained the M.B., B.S. (London) in the same year, proceeded M.D. (with gold medal) in 1910, and took the M.S. and F.R.C.S. in 1912. He was elected F.R.C.O.G. in 1929 and President of the Royal College in 1946. The Royal College of Physicians elected him to its Fellowship in 1947. He is Consultant in Obstetrics and Gynaecology at King's College Hospital and an examiner in the University of Cambridge. The knighthood was conferred on him in the Birthday Honours this year.

Mr Peel qualified at King's College Hospital in 1930 and graduated with the Oxford degree of B.M., B.Ch. in 1932, obtaining the F.R.C.S. a year later. He was elected F.R.C.O.G. in 1944. He is Obstetric and Gynaecological Surgeon at King's College Hospital and the Princess Beatrice Hospital, Consultant Gynaecologist for Puerperal Pyrexia to the Borough of Lambeth, and examiner in the University of London and for the Royal College of Obstetricians and Gynaecologists.

Dr Hall qualified in 1927 at King's College Hospital, taking the D.A. in 1939, he was elected to the Fellowship of the Faculty of Anaesthetics of the Royal College of Surgeons this year. He is Anaesthetist at King's College Hospital.

Sir John Weir was appointed Physician in Ordinary to the King in 1937. He graduated M.B., Ch.B. at Glasgow University in 1907. In 1932 he was created K.C.V.O. and in 1939 G.C.V.O. Sir John is Consulting Physician to the London Homoeopathic Hospital.

## British Council Conference Grants

The British Council has a small fund to enable overseas delegates to attend national or international conferences held in the United Kingdom on scientific subjects, including medicine. Grants are paid to overseas delegates in person and cover subsistence in the United Kingdom for the duration of the conference up to a period of two weeks. Fares to and from the United Kingdom can be paid only in exceptional circumstances. No payment can be made to the convening body to cover their secretarial or other organizing expenses. Grants are made only to delegates who cannot otherwise arrange to come to this country. Conveners of conferences to be held from April 1, 1949, to March 31, 1950, should apply to the Director, Visitors Department, British Council, 3, Hanover Street, W.1, by Jan 15, 1949, giving particulars of their conference and the number of delegates (and their nationalities) who they think will require assistance. Where it is impossible for conveners to apply by Jan 15 they may apply later on the understanding that funds may no longer be available. Applications will be considered by the relevant British Council Advisory Panel of scientific experts, and conference conveners will receive a reply by the end of February, 1949.

## Commonwealth Fund Fellowships

The Commonwealth Fund of New York has established for British subjects a number of Fellowships tenable in the United States. There are three categories of Fellowships, namely, Ordinary, Home Civil Service, and Overseas Civil Service, and all categories are now open to women. Conditions of appointment and tenure and the emoluments attached to the Fellowships may be obtained from the secretary of the Committee of Award, Commonwealth Fund Fellowships, 35 Portman Square, London, W.1, applications for Fellowships to be awarded in 1949 must reach this address by Feb. 1, 1949.

## Guild of St Luke SS Cosmas and Damian

At the annual general meeting of the Guild of St Luke, SS Cosmas and Damian, held at the Hospital of St John and St Elizabeth on Oct 31, the following officers were elected for the forthcoming year: *Master* Dr W B J Pemberton, *Honorary Secretary* Dr W J O'Donovan, O.B.E. (130, Harley Street, London, W.1), *Honorary Treasurer*, Dr P Corridan (114, Harley Street, London, W.1).

## Chief Medical Officer at Colonial Office

Dr E D Pridie has been appointed adviser to the Secretary of State for the Colonies in succession to the late Dr W H Kauntze. The title of the post is now Chief Medical Officer. After serving as Director of Medical Services in the Sudan and in the R.A.M.C. with the Middle East Forces during the war, Dr Pridie was appointed Health Counsellor to the British Embassy in Egypt in 1945.

## Liverpool School of Tropical Medicine

The Liverpool School of Tropical Medicine has been given £10,000 by John Holt and Company (Liverpool) Limited as a birthday gift in honour of the School's inauguration fifty years ago. The generosity of local subscribers and particularly Mr (later Sir) Alfred Jones, a Liverpool ship-owner, made possible the foundation of the School in 1898. It was formally opened by Lord Lister on April 22, 1899. A special ward was set aside for patients in the Royal Southern Hospital, named the Samuel Henry Thompson Ward, it contained twelve beds and it is recorded (*Journal*, April 29, 1899, p. 1036) that at the opening ceremony the nationalities of the twelve occupants represented China, India, the United States, Norway, Sweden, Russia, Finland, England, and Ireland. Major (later Sir) Ronald Ross was appointed Medical Officer.

## Prize for Essay on Colonial Tuberculosis

A prize of 100 guineas will be awarded by the Council of the N.A.P.T. for an essay on "The Control of Tuberculosis in a British Colony". The competition is open to doctors of either sex who are in the service of the Colonial Governments and who are of not more than ten years' or less than five years' medical standing, of which at least three years have been spent overseas in a medical capacity. Competitors should describe their own proposals for a practical scheme for the clinical, social, and administrative control of tuberculosis, either in the British Colonies as a whole or in one or more of them separately. Writers should give their own opinions based on personal experience of public health and anti-tuberculosis work. Essays should be sent to Dr Harley Williams, Secretary-General, National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock Square, London, W.C.1, to arrive not later than May 1, 1949. The award of the prize will be notified at the N.A.P.T. Commonwealth and Empire Health and Tuberculosis Conference in London in July, 1949. Essays sent in shall become the property of the N.A.P.T., and any of them may be published at its discretion in the author's name.

## The Napier Shaw Premium

The Council of the Institution of Heating and Ventilating Engineers has accepted an offer from Mr C G Vokes, M.I. Mech.E., to provide a sum of money to be used to further the science and art of air conditioning and has decided to establish a fund from which it is proposed to make annual awards during the next few years, to be known as the Napier Shaw Premium. The Council announces that Dr T Bedford, D.Sc., Ph.D., Hon. M.I.H.V.E., of the London School of Hygiene and Tropical Medicine, has consented to prepare the first Napier Shaw Premium paper, which it is hoped will be presented at the April, 1949, sessional meeting. The award for 1949 will be made after open competition, and the closing date for submission of papers is March 31, 1949. It is not restricted to members of the Institution. Copies of the regulations will be sent to anyone making application to the secretary, the Institution of Heating and Ventilating Engineers, 75, Eaton Place, London, S.W.1.

## COMING EVENTS

### Congress of Comparative Pathology

The International Congress of Comparative Pathology will hold its fifth meeting in Istanbul from May 17 to 20, 1949. The Congress covers all aspects of human, plant, and veterinary pathology, and considerable latitude is permitted in the choice of subjects for discussion. The British National Committee (chairman Mr T Dalling, C.V.O., Ministry of Agriculture) will be glad to receive as soon as possible the titles of communications which members in this country who hope to attend the Congress wish to submit for transmission to the Secrétaire Général of the Permanent Committee. Arrangements for travelling and hotel accommodation are in the hands of Thos Cook & Son, Ltd. Further information can be obtained from Mr R E Glover (Hon. Sec., British National Committee), Royal Veterinary College, London, N.W.1, or from Pr N R Belger, Taksim, Siriserviler 75/3, Istanbul.

### Leeds University Medical School

The annual dinner for past and present students of the Leeds University Medical School will be held at the Great Northern Hotel, Leeds, on Friday, Nov 26, at 7 for 7.30 p.m., when Dr J T Ingram will preside and the principal speaker will be Lord Moran.

### Aberdeen University Club, London

The Aberdeen University Club, London, will hold a reunion supper and dance at Hyde Park Hotel, Knightsbridge, London, S.W., on Friday, Dec 3 from 7.30 to 11.45 p.m., when Dr W A Milligan will preside. Dinner jackets will be worn, and the price of tickets (including gratuities) is £1 1s each. All Aberdeen graduates and alumni, whether or not members of the club, will be welcome and may bring guests. Arrangements will be made for non-dancers. Tickets may be had from the secretary, Aberdeen University Club Southern Hospital, Dartford, Kent, on or before Nov 26.

## SOCIETIES AND LECTURES

## Monday

MEDICAL SOCIETY OF LONDON, 11 Chandos Street Cavendish Square  
W—Nov 22 8.30 p.m. *Gastroscopy*. Discussion to be introduced by Dr Avery Jones and Mr Hermon Taylor

## Tuesday

CHADWICK TRUST—At Royal Sanitary Institute, 90, Buckingham Palace Road London, SW Nov 23, 2.30 p.m. *Bossmom Gift Lecture The Influence of Hygiene on the Shape of Buildings* by Mr A MacDonald

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Edinburgh Royal Infirmary (West Medical Lecture Theatre) Nov 23 5 p.m. *Renal Failure* by Professor R Platt

INSTITUTE OF DERMATOLOGY 5 Lisle Street, Leicester Square London, WC—Nov 23, 5 p.m. *Abnormalities of the Cutaneous Circulation in the Lower Limb* by Mr A K Monro

INSTITUTE OF UROLOGY—At St Paul's Hospital Endell Street London, WC Nov 23, 11 a.m. *Tuberculous Dorsalis* by Dr J C Hawksley, at St Peter's Hospital Henrietta Street London, WC Nov 23, 5 p.m. *Retropubic Operations on the Prostate* by Mr A W Badenoch

ROYAL COLLEGE OF PHYSICIANS OF LONDON Pall Mall East, SW—Nov 23, 5 p.m. *Victorian Medical Administrators and Their Significance for To day* Bradshaw Lecture by Dr J A Charles

## Wednesday

INSTITUTE OF UROLOGY—At St Paul's Hospital Endell Street London, WC, Nov 24 11 a.m. *Syphilis of Skeletal System* by Dr W N Mascall at St Peter's Hospital Henrietta Street London, WC, Nov 24, 5 p.m., *Endoscopic Resection of the Prostate* by Mr R Ogier Ward

PLANNING FORUM—At Planning Centre Hall, 28 King Street, Covent Garden, London, WC, Nov 24 6.15 p.m. *Work and Health* discussion to be opened by Dr R S F Schilling, Mr Brian Punch, and Dr John Burton

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242 St Vincent Street Glasgow—Nov 24, 5 p.m. *Vascular Surgery* Dr John Burns Lecture by Mr A Dickson Wright

SOCIETY OF CHEMICAL INDUSTRY FINE CHEMICALS GROUP—At London School of Hygiene and Tropical Medicine Keppel Street WC, Nov 26, 7 p.m. *Some Aspects of the Relationship Between Chemical Constitution and Physiological Activity* by Dr F Bergel, D Phil Discussion

SURREY COUNTY MEDICAL SOCIETY—At Dorking County Hospital Nov 26, 7 p.m. Clinical meeting

## Saturday

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY (University of London)—Nov 27, Annual clinical 'At Home' at the hospital. The annual dinner will be held in the evening at the Savoy Hotel

## APPOINTMENTS

BLAKE H ELLIOTT FRCS Plastic Surgeon St George's Hospital London SW

DAVIES IDRIS MD MRCP DPH Medical Adviser for Wales in connection with resettlement in employment of men and women disabled through war service of industrial diseases

GUMLEY G A H MD MRCPED DPH Group Physician West Fife Hospitals Group South East Regional Hospitals Board for Scotland

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London WC—Assistant Medical Registrar to the enteritis Unit J A Black, Macoun MB BCh MRCP, T R Savage BM BCh MRCP House Surgeon to Orthopaedic Department R J Cowan MD Assistant Resident Medical Officer (Tadworth Court) Pamela A Davies MB ChB

HUTCHINSON W J MB BCh DPH Deputy Medical Officer of Health Great Yarmouth

JOHNSTON W R MB BCh DPH Assistant Medical Officer of Health for Londonderry Northern Ireland

LESSLIE ADRIAN J M MB ChB DPH Senior Medical Officer for Maternity and Child Welfare in Wolverhampton

LONDON COUNTY COUNCIL—Divisional Medical Officer G O Mitchell MD MRCP DPH, Officers Elsie J Madeley MB ChB DPH Eve A M White MRCS, ChB DPH Evelyn Russell MD

MICHE A MCG MB ChB DPH Medical Superintendent for Aberdeen General Hospitals

OWEN G D MD Physician (part time) to Northallerton Hospitals

ST ANDREW'S HOSPITAL, Bow London E—Senior Resident Anaesthetist J Hamilton MB ChB DA Assistant Medical Officer Class I J T Bolger MB BCh

TAYLOR M OBE MD DPH Medical Officer of Mental Health for the North East Region Aberdeen

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTHS

Carey—On Nov 3 1948 at Liverpool Maternity Hospital to Margaret wife of Dr A S Carey a son—Michael Stuart

Jackson—On Nov 7 1948 at Middlesex Hospital London W to Lesley (née Bellamy) wife of Mr Ian Jackson FRCS a son—Patrick

## DEATHS

Alexander—On Nov 3 1948 at Bowmont Villa Kelso Stuart Maxwell Alexander MB ChB Ed

Blomfield—On Nov 9 1948 at West Middlesex Hospital Isleworth Joseph Blomfield OBE MD aged 78

Bodger—On Nov 3 1948 at Ridgemount Asitwood Bank Redditch Septimus Bodger MD aged 80

Dalyell—On Nov 1 1948 at Greenwich Sydney NSW Elsie Jean Dalyell OBE MB

Deane—On Nov 8 1948 at Meadowland Old Road Headington Oxford Archibald Deane MD

Dickey—On Oct 28 1948 at Huigra Ecuador Herbert Spencer Dickey MD aged 72

Ferrar—On Nov 8 1948 at 103 Anglesca Road Dublin Benjamin Banks Ferrar MD MRIA formerly Superintendent of the Zoological Gardens Dublin

Gillespie—On Nov 9 1948 at Barrowmore Milnathort David Gillespie MC MD late of 29 Roslyn Hill Hampstead NW

Griffiths—On Nov 3 1948 at Derwydd Cross Hands Llanelli Carmarthen shire David Henry Griffiths MRCS LRCP

Healey—On Nov 4 1948 at Carrobreck Lower Helleston Frederick Henry Healey MD DPM aged 48

Hinde—On Nov 8 1948 Francis Richard Berthon Hinde MD Ed

McGregor—On Nov 7 1948 at 298a Earls Court Road London SW James McGregor LRCPS Ed and LM late of Portsmouth aged 89

McLeman—Recently John McLeman MB ChB Ed of Greenock Renfrew shire

Mather—On Nov 6 1948 Norman James Urquhart Mather MB BCh BAO

Spurr—On Nov 5 1948 at 28 Mount Pleasant Norwich James Spurr MRCS formerly of Lyme Regis and Winchester aged 90

Tighe—Recently Vincent Paul Tighe LRCPSI and LM of Dublin

Williams—Recently at Vauxhall House Llanelli Carmarthenshire Sydney Williams MRCS LRCP aged 68

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Lactation in Virgins

**Q**—In her book *Sex and Temperament* (1935 Routledge p 193), Margaret Mead the American ethnologist describes how one of the savage tribes in New Guinea adopts babies who are then breast fed by women who have never had children of their own. She claims to have compared two such cases in which adopted children suckled by mothers in whom lactation had been artificially stimulated grew just as well as their twin brothers or sisters. This observation if correct would seem to contradict all our knowledge of lactation. What is the explanation?

**A**—The occurrence of lactation in virgins has been described from time to time, and several cases are mentioned by D C L Fitzwilliams in his book *On the Breast* (1924, London, Heinemann). In all these cases lactation was induced by suckling, and the phenomenon is recorded even at 8 years of age (in a virgin negress). He also notes similar occurrences in men and in extremely aged parous women. Full details are not given, but there is nothing to suggest that these individuals had any disease of the pituitary or other endocrine organs. Our present knowledge of the physiology of lactation is not so complete as to rule out the possibility of the events described in the question. Indeed, the more that is learned of this function and its control, the more complicated it becomes. Although it is fairly well established that the onset of lactation in the human being is brought about by a hormone of the anterior pituitary acting on breasts already primed by oestrogens and progesterone (and possibly by other anterior pituitary factors), it also seems clear that the maintenance of lactation is essentially the result of suckling. There is some difference of opinion about the mechanism whereby suckling acts. Some believe that it is purely local, that the regular emptying of the breasts favours further secretion, others consider that there is a nervous reflex and that suckling stimulates the anterior pituitary to release more prolactin, and also that it stimulates the posterior pituitary to liberate a factor which causes contraction of the muscular tissue around the lacteal ducts. Emotional factors also possibly play a part, and a well-developed maternal solicitude for the child may influence the lactogenic function of the pituitary. If the latter views are correct, it seems feasible that, in certain susceptible women with an overwhelming desire to look after a newborn child, regular suckling might prove a sufficient stimulus to the pituitary to initiate lactation.

### Faecal Incontinence in the Aged

**Q**—What is the treatment for lack of control of the sphincter in old people without any obvious local cause?

**A**—Both urinary and faecal incontinence are common penalties of old age. Some interesting observations by Wilson (*Lancet* 1948, 2 374) have recently shown the former to depend largely on an overactivity of the neuromuscular mechanism of the bladder. He found that weakness of the sphincter was a rare cause. In some the disturbance depended on local irritative factors, and the common reason was loss of cortical control. The bladder and the rectum are so similar in function that it seems probable that his observations can be applied to the faecal incontinence of the aged, although general experience suggests that loss of tone of the sphincter is likely to play a more important part in the latter. Treatment is not satisfactory. Improvement will normally follow measures to inculcate the regular bowel habits from which frequently the patient has lapsed. It is wise to avoid purgation and to ensure a well-formed stool by means of a diet containing adequate roughage. The aim is to secure a complete evacuation at a fixed hour each day, and the patient should be instructed to go to stool after breakfast even in the absence of the normal urge. If

there is no spontaneous evacuation resort must be made to enemata, which have the effect of re-educating the bowel. Impaction of faeces in the rectum is a cause of apparent incontinence and may demand digital evacuation.

### Rubella in Pregnancy

**Q**—Are any statistics available regarding the incidence of blindness partial or complete in the newborn infant of a mother infected with rubella? What is the pathology of the condition?

**A**—It is generally accepted now that an attack of rubella in the mother during the early months of pregnancy leads to ocular and other congenital anomalies in the offspring. The frequency of these occurrences has not been established, and it is obviously impossible that they should be until a large number of expectant mothers with rubella have been followed up systematically. As the time factor is important (rubella late in pregnancy appears to be harmless) the difficulty in giving statistics is still further increased. In general terms, it is probably correct to say that rubella in the mother is of little significance for pregnancy as a whole. It is of considerable significance in the second and third months of pregnancy, and it is possible that an attack of rubella even before conception may also be of importance, as the persistence of the virus after the acute attack has passed off may still influence the developing embryo. Whether rubella in the early months of pregnancy must inevitably lead to congenital malformations in the offspring is not known, such evidence as is available suggests that they are the exception rather than the rule. It is known from experimental embryology that disturbances in the chemical and physical environment of a growing embryo have serious results and may lead to the death of the embryo. It is presumed that the mechanism in rubella is the passage of the virus through the placenta (which normally acts as a barrier against most noxious agents) so that the embryo is exposed to the action of this virus. When organs are fully formed the effects are slight, or there may be none at all. With organs still in the stage of active formation the outcome may be disastrous. This conforms to the findings in experimental embryology that the effect of noxious agents is more pronounced during the early stages of development than later.

### Calciferol in Hilar Adenitis

**Q**—It is believed that calciferol in daily doses of 100 000 to 150 000 units produces shrinkage and calcification in tuberculous cervical adenitis, can the same be said for the enlarged hilar glands in primary tuberculosis? If so is calciferol to be recommended? Can safety in its use be presumed when careful clinical observation is maintained and the administration promptly stopped on the appearance of any indication of toxicity? Can any therapeutic effect be expected where the dosage is well below the tolerated maximum?

**A**—Whereas there is no doubt of the value of calciferol in cutaneous tuberculosis, its effectiveness in other forms of the disease has not yet been fully estimated. However, there have been encouraging reports of its use for glandular lesions. There would appear to be no contraindication to the use of this drug in tuberculous hilar adenitis provided proper precautions are observed. Judging by experience in the treatment of cutaneous tuberculosis, it is most unlikely that small doses would be of any value.

### Toxic Effects of Amphetamine

**Q**—In prescribing amphetamine for chronic states of depression in a woman of 40 are there any toxic effects of a prohibitive nature that might develop on prolonged administration—say four months? Over such a relatively long period has the drug any permanent effects on the central nervous system which would lower the mental capacity for, say shorthand-typing?

**A**—Prolonged administration of amphetamine in the patient described may be accompanied by (1) a growing feeling of irritability and nervousness, (2) aggravation of sleeplessness if this is present, (3) increased depression as the effect of each dose wears off, and (4) a liability to fainting attacks. There will be a loss of appetite, which will be a good thing if the

patient is obese but bad if she is thin. None of these effects are reasons against trying this drug but a watch must be kept on the patient. There is no evidence that amphetamine produces permanent effects on the central nervous system or any lowering of mental capacity.

#### Residual Pelvic Abscess

**Q**—About a year ago a woman of 35 was operated on for a perforated appendix; she developed a pelvic abscess a week later which burst into the rectum. After a long convalescence she is now fairly fit but still has occasional looseness of the bowels with discharge of pus. She was recently free from symptoms for a whole week. Is the condition likely to recover spontaneously? Is radiological investigation by barium enema free from risk? Is further surgery necessary?

**A**—A pelvic abscess discharging spontaneously into the rectum should heal automatically within a few weeks. The year that has elapsed in this case would seem to make some investigation imperative, and a barium enema should be perfectly safe. Presumably the residual abscess cavity is completely walled off by fibrous tissue. This same fact indicates the line of treatment, which should be a wider opening of the residual cavity into the rectum if the region concerned is reasonably accessible. It might be presumed that failure of resolution has been due to inadequate natural drainage and that possibly further and more adequate opening of the existing communication with the bowel may achieve the required result.

#### Persistent Nasal Catarrh

**Q**—For the past year a child of 6 has had moderate nasal catarrh, shown by snoring at intervals and by mucus being blown from one nostril perhaps two or three times a day. The child mouth-breathes by day but sleeps with the mouth closed and there is no snoring or cough. What treatment should be given and particularly is adenoidectomy advisable?

**A**—The symptoms suggest chronic sinusitis, probably associated with adenoids, but it should be possible to make a definite diagnosis by skiagrams and by mirror examination of the naso-pharynx. If there is sinusitis only, instillation of 0.5% solution of ephedrine in normal saline night and morning should suffice. If adenoids are present or suspected they should be removed and the intra-nasal punctured and washed out under short general anaesthesia.

#### Vitamin K and Menstruation

**Q**—An unmarried woman aged 37 took normal doses of vitamin K last winter for chilblains. It proved highly successful and she is anxious to take it again this winter. Since January however she has had only one menstrual period—in April. There is no other apparent cause for the amenorrhoea. Is there likely to be any connexion between the vitamin K and the amenorrhoea and if so is this a contraindication to its use?

**A**—In the doses in which vitamin K is used it has no effect whatsoever on the menstrual cycle. In fact large doses have been given experimentally to suppress menstruation and to treat menorrhagia, but without effect.

#### Treatment of Peripheral Vascular Disease

**Q**—A male aged 76 suffers from severe pain in his left leg due to atheroma of the arteries. He has no pain when in bed but suffers acutely when sitting or walking. On rising from a chair he has to stand for a few moments before he can move. Apart from the local condition his general health is excellent and his heart sound. Can you suggest any drug which I could prescribe?

**A**—It is not common for peripheral vascular disease to cause pain when sitting in a chair but not when lying unless erythromelalgia—in which pain is aggravated when the limb is dependent—is present. The medicinal treatment is twofold: by means of simple analgesics and by reputed vasodilators. The effect of the drugs of the second group is unpredictable, although usually disappointing; they should always be given as a trial. Papaverine hydrochloride 4 to 1 gr (32 to 65 mg) subcutaneously or by mouth, acetyl- $\beta$ -methylcholine 0.1 to 0.5 g. orally, theobromine sodium salicylate 10 to 15 gr (0.65 to 1 g) and nicotinic acid

50 mg have all been recommended and may be used in these doses three to four times daily. Dried thyroid is sometimes useful. More patients are helped perhaps, by physical methods such as intermittent venous occlusion.

## NOTES AND COMMENTS

**Lactating Baby**—Dr J C VALENTINE (Lecturer in Pathology in the University of Bristol) writes: In reply to a question regarding the treatment of lactation in an infant (Oct 23, p 768) you suggest the administration of testosterone. While on theoretical grounds this might be of value—since it is known to be effective in inhibiting milk secretion in women—there is some evidence that it may not be effective in the newborn infant. Slobozanu<sup>1</sup> injected testosterone intramuscularly into male and female newborn infants and found that the incidence of enlargement and milk secretion was thereby increased. He did however, find that with large doses there was some inhibition of milk secretion but even with 25 mg doses 12% of the boys secreted milk.

Another method commonly used to inhibit lactation in women is the administration of oestrogens natural or synthetic. Dr Margaret Robinson<sup>2</sup> has found that in the newborn the application to the breasts of lint soaked in a 5% solution of stilboestrol in arachis oil followed by gentle expression of the milk, soon relieves the engorgement. On the other hand Slobozanu injected oestrone intramuscularly into newborn infants and found that this resulted in an increased incidence of mammary enlargement and milk secretion. It would be of interest to know the effect of oral or pre-natal administration of stilboestrol. There is additional support for Slobozanu's work in the papers of Abraham<sup>3</sup> and Dobszay<sup>4</sup>. Abraham found that by the injection of oestrin he was able to cause mammary enlargement and secretion in the newborn to return after they had ceased, and Dobszay was able to induce mammary enlargement in the newborn by the injection of oestrin, and then by the injection of pituitary mammotropic hormone, was able to induce colostrum secretion.

**Calcium Iodide for Cataract**—Mr SYDNEY TIBBLES (London, W 1) writes: In 'Any Questions?' (Oct 2, p 667) the question and answer given were pretty much the same as those to which I gave a fairly full explanation of my own experience in the *Journal* of Sept 6, 1947 (p 404). This provoked no protests but produced many medical men with cataract, one of whom was a well-known eye surgeon, while another, in the late forties, put the commencement of his troubles down to convulsive treatment given for some mental breakdown. In thirty odd years of using iodides for early lens changes I can only think of four that had to be operated on in the end, and many of my cases have attended and have come back regularly, some for as long as twenty five years. Two patients with early changes in both eyes have, as test cases, been told to use the treatment for one eye only for the past four or five years, but in each case the eye that had no treatment became worse than its fellow. In the end treatment was commenced for the second eye. This iodide treatment does not profess to cure cataract, but apparently in a very large number of early cases the degenerative changes can be controlled for a large number of years. Before July 5, 1948, a very much larger number of cataract patients in an advanced stage were seen in hospital as compared with private practice. Patients who have to travel a long way to hospital wasting half a day off from work often put off their troubles till one eye is blind and the other beginning to fail before they seek advice. The great advantage of eye clinics such as those sponsored by the B.M.A. (National Eye Service prior to the new N.H.S. scheme) was that the patient could make an appointment to suit himself and seek advice somewhere near where he lived.

**Correction**—Mr E W RICHES (London W 1) points out that in our report of the meeting of the Medical Society of London held on Oct 25 (Nov 6, p 831) it was wrongly stated that he spoke on the use of streptomycin in tuberculous infections of the urinary tract. His paper was concerned with non tuberculous infections.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 20 1948

## National Health Service

### DOCTORS' FALL IN INCOME DISCUSSION WITH MINISTRY

Members of the Insurance Acts Committee met the Secretary and other officials of the Ministry of Health on Nov 17 and discussed reports which have reached the Association from all parts of the country that doctors, particularly in small towns and semi rural areas where conditions are such that it is impossible to acquire a large list of public patients, are suffering a severe fall in income as a result of the new Service.

The profession's representatives urged steps to relieve the position of badly hit practitioners, making a number of suggestions for immediate action pending the review of remuneration now being undertaken by the Committee and likely to be completed in the next few weeks.

A fuller report of the representations made will be published in these columns next week.

### G.P.s' MILEAGE FUND "WEIGHTING" SCHEME PROPOSED

At present the annual mileage fund is £1,300,000, which is deducted from the £40,000,000 in the central pool. Before the war the fund in the N.H.I. Service was £250,000, and before the National Health Service began it was £600,000.

The International Distribution Committee will decide what proportion of the fund goes to England and Wales on the one hand and to Scotland on the other, the National Distribution Committees will then allocate the proportions to be paid to each executive council, and the executive council will pay the individual general practitioner in accordance with the number of units of mileage or walking he claims. It is not possible to say what the value of this unit will be until all the claims are known.

Mileage payment is a method of compensating a rural practitioner for his being unable to take on his list as many patients as his urban colleague can, and for his having greater difficulty in getting to his patients—apart from such special difficulties as are to be covered by the Special Inducements Fund. It has therefore been recommended to the Ministry that the mileage units claimed by practitioners should be weighted so that they bear the following values: for the urban practitioner 1, for the semi-rural practitioner,  $1\frac{1}{2}$ , and for the rural practitioner, 2. The classification of practices for this purpose would be the task of the local medical committees.

### VISITS TO OUTLYING HOSPITALS INTERIM RATES OF PAY

There seems to be some diversity of policy in the various Factors about payment in cases where specialists are asked to visit patients at hospitals of which they are not members of staff. In the permanent arrangements it is probable that

the liability to undertake such calls will be taken into account in assessing the specialist's remuneration. For the time being, however, payment should be made as for an additional session—i.e., at the rate of £4 4s a visit, whatever the services rendered.

### ALLOCATION OF PAY-BEDS ALTERED PROPORTIONS REPORTED

It appears that in certain regions hospital boards are disturbing the proportion of pay-beds to public beds, and representations have been made to the Ministry regarding this apparent breach of the Minister's assurance that the distribution of pay-beds will be allowed to lie as at the appointed day during the interim period. The Ministry has pointed out that in cases where there is a waiting-list for public beds a regional board has an obligation to use any vacant private beds, but that any proposals for the permanent reallocation of pay-beds must be submitted for the approval of the Ministry. An assurance has been given by the Ministry that no such proposals have as yet been received or approved by the department.

### REPORT OF COMMITTEE ON PARTNERSHIPS

Mr Bevan stated in a written answer on Nov 11 to Mr Linstead's question about the report of the Legal Committee on Partnerships (*Supplement* Nov 13, p 170) "I received this report on Nov 8 and am considering it."

### DOMICILIARY VISITS TO PRIVATE NURSING-HOMES

The Ministry has ruled that the domiciliary arrangements are not available to patients in private nursing-homes. The Central Consultants and Specialists Committee, whilst appreciating the possible repercussions on specialist private practice if domiciliary visits to private nursing-homes are permitted under the public service, had in mind cases where treatment in a private nursing-home is recommended because the patient's home surroundings are unsatisfactory. Many maternity cases would come into this category, which would also include the elderly invalid patient who permanently resides in a private nursing-home. This matter is being examined and will be discussed by the Committee.

### MIDWIVES

The position of midwives in relation to doctors giving maternity services under the National Health Service has been clarified by the Ministry (Circular Letter 173/48). If a practitioner has been engaged to deliver the patient, has been notified of the onset of labour, and continues to be in charge throughout the lying-in period, then the midwife is deemed to be acting as a maternity nurse. (Details are given under "Local Administration," p 181.)

## FELLOWSHIP FOR FREEDOM IN MEDICINE CAXTON HALL MEETING

A Fellowship for Freedom in Medicine was formed at a very largely attended meeting of members of the medical profession held at Caxton Hall Westminster on Saturday afternoon, Nov 13. The number of those present was well over 700 and during the two hours discussion, except on the choice of name for the new body, there was no division of opinion. On the proposition of Dr R Hale-White Lord HORDER was unanimously acclaimed to the Chair.

### Chairman's Statement

Lord HORDER began with a reminder of the origin of the meeting—a letter above his signature in the *British Medical Journal* of June 19. The response to the invitation contained in that letter was prompt and unexpectedly large. The earlier letters came from men and women who had not joined the Service, later, in increasing numbers, from those in the Service. To date some 1,750 letters had been received and they were still arriving at the rate of 15 to 20 a day. Hundreds of the letters contained constructive ideas. To help in their analysis he nominated six colleagues, later extended to twelve, who formed an interim committee.

That day he hoped they would not spend much time on a post mortem. The Special Representative Meeting of May 28 gave the profession its last chance of resisting dragooning by politicians, and the chance was thrown away, he had called it "the triumph of the machine." Some of the dominant factors that entered into the tragic situation "which developed between January, when we marched so unitedly and effectively, and May, when, more like a rabble, we surrendered," could be stated. Among them were

"a secretariat swollen in numbers and influence, much going and coming between it and Whitehall, too strong a tail wagging too weak a dog, machinations, thought by many to be both meddlesome and mischievous, on the part of men holding key positions outside the [British Medical] Association"—(applause)—"and, if I may plagiarize Milton, 'blind mouths' at the centre and at the periphery hungry sheep looking up but not being fed."

He felt that from the very start, much earlier than the recent collapse, the medical profession had lacked a due appreciation of its value in society. "We let ourselves be used as pawns in the game instead of being master pieces. We scarcely dissented when the Minister called his *ipse dixit* a 'consultation'." Their own weakness was partly responsible for the fact that the National Health Service was "born in dishonour," for they allowed themselves to be a party in the mad precipitancy of the Government whereby the public was made to contract for health benefits which did not exist.

### The Result of It All

The living power of medicine, Lord Horder continued, resided as it must always be in the personnel of the profession, had passed out of its hands to be lost, for a time, in the dead machinery of the bureau.

Medicine has indeed become, what we pledged ourselves it never should become a branch of the Civil Service. The fruit which was not yet ripe has become very ripe by hothouse treatment and the Minister has plucked it. We are no longer experts. We sit and sign forms. With no time to diagnose their diseases we pass our patients to other persons and to institutions knowing full well that these cannot dispense the health benefits which may or may not be needed. In the economic field doctors have been manoeuvred into surprising positions. Some are faced with serious financial insecurity. Others are making bigger incomes than they formerly did but are doing less doctoring in return. And the galling thing is that it is Dr Peter who is paying Dr Paul."

What to do about it? The proper thing to do was to pull themselves together and consider how best as doctors and in the public interest they could recapture their freedom and safeguard it in the future. Had the standard of medicine fallen and was it likely to continue to fall? The large correspondence which had come their way suggested that the answer was yes. He did not see how it could be otherwise. The essence of good doctoring was diagnosis and diagnosis called for time and a close-up with the patient, denied at the moment to

thousands of practitioners. Good doctoring called also for a feeling of satisfaction on the part of the doctor in the work he was doing and a sense of economic security. For many doctors now the savour had gone out of their work and their sense of security also had been rudely shaken.

It had seemed therefore desirable to form some sort of body through which the purpose of those concerned to recover and maintain the freedom of medicine might be canalized. Should it be a trade union? God forbid! A guild? That he felt was the idea, but there might be legal difficulties. But, whatever the name the object was to keep the standard of British medicine and doctoring at a high level and to assist the State in making the best that was in medicine available to the whole community.

The relation of our new body to existing organizations will come up for discussion. My own views are very simple. Our hand should be against no man. We are a break-away from no other body. If and when we are confident that the B.M.A., whether by reorganization or otherwise, and/or the Royal Colleges accept, and carry out, the obligation to the public for which we ourselves stand, we can dissolve into thin air. But that time is not yet."

In conclusion Lord Horder averred himself still an optimist. That meeting had reinspired him. As he had said in an address to the Cardiff Medical Society four years ago, he still saw hope for themselves as doctors. "We have not yet forfeited the trust of our patients, we have not yet bartered our spirit of adventure for a mere hope of security." They were there as the custodians of medicine for their patients. But let them look to their charge. To day it needed all their vigilance and all their care.

The address was punctuated by expressions of approval from the large audience, and there was loud cheering at the close.

It was proposed and seconded from the body of the meeting that a body should be formed whose aim would be to safeguard the freedom of medicine, and although one speaker wished to enlarge the conception beyond medicine, to embrace freedom as a general philosophy and ethic, so that the new body would be an association of medical men standing for the protection of freedom in all spheres, the narrower conception of the freedom of medicine was accepted by the meeting. Lord Horder pointed out that their contribution was to medicine and by enlarging their target they might hit nothing of importance.

### Naming the Child

Several names were suggested for the new body. One suggestion was 'Association to Safeguard Medical Independence', another was 'British Medical Guild,' but it was pointed out that this would require a legal charter, another was "Society for the Protection of the Freedom of Doctors", yet another 'The Fellowship of Medical Freedom' and one more, 'Medical Freedom League'.

Dr E C WARNER said that the interim committee had spent some time over this subject and had arrived at the compromise title of 'Association for Freedom in Medicine'. Dr S F L DABNE seconded the adoption of this term, which was very generally supported. Dr H H D SUTHERLAND hoped that "Association" would not enter into the name of the new body, and proposed the more intimate word "Fellowship," and this amendment was carried, so that the name chosen was 'Fellowship for Freedom in Medicine'.

### Membership

Lord HORDER suggested that all medical men and women should be eligible for membership, and this was accepted.

Dr TAYLOR (Purley) thought that those who were not in the Service should form the inner core of the new Fellowship. He was not suggesting that those who were working in the new Service should be excluded, but they should on joining be required to make a declaration that they were only in the Service because of economic or other pressure and under protest, and that they did not agree with the nationalization of doctors.

The CHAIRMAN. The essence of this body is a forum in which various views can find expression. Of the thirty letters which came in to-day more than half are from men and women in the Service. As to the core, I was hoping 'there wasn't going to be no core'.

Dr Taylor's suggestion did not commend itself to the meeting.

## for prolonged local medication

Penicillin Chewing Gum A&H presents penicillin incorporated in a base predominantly mint-flavoured and designed to maintain the potency of the medicament

When chewed slowly it provides an effective concentration of penicillin in the mouth for three to four hours. It is thus the preparation of choice in the treatment of Vincent's infection, tonsillitis and other buccal and pharyngeal infections due to penicillin-sensitive organisms

### PENICILLIN CHEWING GUM A&H

# CREMOMERAZINE

palatable

suspension

of

## SULPHAMERAZINE

readily acceptable to  
children and adults

CREMOMERAZINE is a pleasantly flavoured and extremely palatable suspension of Sulphamerazine which has been reduced to a fine state of subdivision, thereby ensuring rapid absorption into the blood stream

CREMOMERAZINE presents the clinical advantages of Sulphamerazine viz rapid absorption, slow excretion, reduced toxicity and less frequent dosage, in a form that is ideally suited for administration to young children

CREMOMERAZINE contains in each teaspoonful the equivalent of one tablet (0.5 Gm) of Sulphamerazine

CREMOMERAZINE is indicated in the treatment of meningococcal, pneumococcal, haemolytic streptococcal and gonococcal infections and in rheumatic fever prophylaxis

CREMOMERAZINE is supplied in 4 oz and 16 oz bottles

Informative literature gladly forwarded on request

SHARP & DOHME LTD, HODDESDON, HERTS

# chilblains

IN CROOKES IODINE OIL the somewhat violent characteristics of iodine have been brought under control. Thus the oil is non staining, rapidly penetrative and free from irritation.

Following its application the oily medium may be removed by the use of any dry material leaving a protective film which is harmless to clothing.

These characteristics are of particular value when Crookes Iodine Oil is used for the treatment of chilblains. Absorption of the iodine immediately follows the lightest movement of the oil over the affected part—an ease of application which greatly facilitates its use. It is indicated for both broken and unbroken chilblains.

## Crookes Iodine Oil

Supplied in 1 oz. & 1/2 oz. bottles. Also available with 10% methyl salicylate.

THE NEW CROOKES PRICE LIST WITH THERAPEUTIC INDEX AND DESCRIPTIVE NOTES WILL BE GLADLY SENT UPON APPLICATION. THE CROOKES LABORATORIES LIMITED PARK ROYAL LONDON N.W.10

One speaker proposed that medical students be admitted, but the proposal was not pressed, the Chairman pointing out that any medical student who thought for himself would keep an eye on what they were doing and be ready to join on qualification

### Relations with Other Organizations

In introducing this question the Chairman said he had already suggested that their symbol should be the open hand, not the closed fist. They were ready to welcome all who shared their views. He hoped that the spirit of the meeting itself would go some way to correct a number of statements to the effect that they were antagonistic to existing bodies, meaning in particular the B.M.A. Already four members of the B.M.A. Council had addressed the meeting that afternoon.

Dr J. A. GORSKY said there were reasons why the new Fellowship should not go out to the world as a breakaway body from the B.M.A. ("Hear, hear") A committee had been set up by the B.M.A. Council, following a debate which he himself initiated at Cambridge, for the purpose of considering the constitution of the Association. He was proceeding to develop this point, when the Chairman intervened to say that the reconstitution of the B.M.A. was a matter for the B.M.A. itself.

Dr GORSKY: I am not attempting a post mortem, I am attempting—(The Chairman: "A resurrection") (Laughter)

Dr A. V. RUSSELL proposed

That this Fellowship is not in opposition to any other existing medical organization, but is ready to strengthen their hands in so far as they are prepared to work for the maintenance of medical freedom.

This was seconded and, on the understanding that the Executive Committee presently to be appointed would explore the phrase "strengthen their hands," was carried.

Dr L. W. BATTEN moved briefly, and Dr A. C. E. BREACH seconded without a speech.

"That as this body is deeply disturbed by the way outside influences may affect the quality of medicine in this country, it is determined to do everything in its power to render the highest standards of practice possible in the future."

This was immediately carried unanimously.

### Officers and Committee

Dr JOHN COWAN (Manchester) moved the election of Lord Horder to the chairmanship of the Fellowship. He said that they all owed a great debt of gratitude to him. He had been the inspiration and guiding force of the whole of this movement. Not only those assembled there that afternoon and their colleagues who had been unable to attend that meeting, but the future practitioners of medicine in this country, had occasion to be profoundly grateful for what he had done.

The proposal was unanimously adopted.

Lord HORDER then suggested the names of Dr R. Hale-White for the Vice-Chair, Mr Reginald T. Payne for the Honorary Treasurership and Dr E. C. Warner and Dr G. H. Rosedale as Joint Honorary Secretaries. These names were agreed to.

For the Executive Committee, he stated that it had been thought that a membership of 20, over and above the five officers who were *ex-officio* members, would make it possible to secure adequate representation both of the different parts of the country and of the different branches of medicine.

It was agreed to fill only half the Executive seats at the moment, leaving the other half to be nominated by the Executive with a view to getting an all round representation. Those nominated and elected at the meeting were the following:

Dr Barbara Abercrombie (Liverpool), Dr A. C. E. Breach (Warrington), Dr S. F. L. Dahne (Reading), Dr D. R. Goodfellow (Manchester), Dr G. M. Goodwill (Attleborough), Dr Frank Gray (London), Dr A. V. Russell (Wolverhampton), Dr Campbell Shaw (Bournemouth), Dr J. G. Thwaites (Bristol), Dr K. D. Wilkinson (Birmingham).

The meeting further agreed that the minimum annual subscription should be one guinea so as not to exclude any on account of expense but it was hoped that as many as were possible would subscribe more.

Dr D. R. GOODFELLOW proposed the final resolution.

"That the Executive Committee be asked to consider ways which freedom in medical matters can be best preserved by the profession."

He said that he had always felt that the Law, the Church and Medicine should be beyond the reach of contamination by political control. The Health Service had come to stay, but it was the wrong sort of Health Service, it was all cock-eyed at the moment and had to be straightened out.

The resolution was seconded by Mr E. H. RICHARDS and carried unanimously.

It was agreed that a draft constitution of the new body should be prepared by the Executive, with legal help, and brought before the next meeting.

The CHAIRMAN said that the date of the next meeting could not at the moment be given. As for the place, he thought it might be desirable to meet in a provincial centre as so many of the supporters of the movement were from the provinces. Indeed, an analysis of the geographical distribution of the forms returned showed that the sympathizers with and potential members of the Fellowship were to be found as far north as the Hebrides and as far south as the Lizard. It was left to the Executive Committee to make the necessary arrangements.

The assembly gave Lord Horder an ovation at the end of the proceedings, and the gathering dispersed to the strains of "He's a jolly good fellow."

\*\* We understand that some of those nominated and elected as members of the Executive Committee have not yet decided to serve. Dr Frank Gray and Dr J. G. Thwaites, for example, ask us to state that they have not accepted membership of the Committee.—Ed., B.M.J.

## Local Administration

*We publish below information from some of the Ministry circulars sent to local bodies working under the N.H.S.*

### Midwives

The Minister's Circular 173/48 to local health authorities and executive councils states: "Maternity medical services under Part IV of the National Health Service Act were intended to supplement—not to replace or detract from—the midwives service provided by the local health authorities. It has, however, come to the Minister's notice that there is uncertainty in some areas whether a midwife booked by an expectant mother who has arranged for a doctor to give her maternity medical services under Part IV attends the mother as a practising midwife or as a maternity nurse. The local health authority will now have received the letter sent to them, as local supervising authority under the Midwives Acts, on Oct 29 by the Central Midwives Board, in which the following statement on this question is made for the guidance of domiciliary midwives:

"The Board regards the midwife as acting as a midwife unless all the conditions laid down in Rule E 20 are fulfilled. If they are all fulfilled then she is deemed to be acting as a maternity nurse. Hence the acceptance by the medical practitioner of responsibility for the provision of maternity medical services and the carrying out of antenatal care by him does not affect the position of the midwife who is acting as such, but if the doctor has stated specifically that he wishes to be summoned at the onset of labour and that he proposes to deliver the woman himself she is in that case acting as a maternity nurse."

"The Minister wishes to express his full concurrence in the Board's statement."

Rule E 20 of the Central Midwives Board is as follows:

In this Part of this Section of the Rules, unless a contrary intention appears, the following expressions have the meaning hereby respectively assigned to them: "midwife" means a woman whose name is on the Roll of Midwives, "maternity nurse" means a midwife who, in any maternity case, is acting under the direction and personal supervision of a registered medical practitioner who (i) has been engaged to deliver the patient, (ii) has been notified of the onset of labour, (iii) continues to be in charge of and responsible for the case throughout the lying-in period.

Note—Unless all the foregoing conditions are fulfilled, the midwife is deemed to be acting as a practising midwife, and as such

ject to the Rules set out in Part II of this Section of the Rules the midwife is in any doubt, she should regard herself as acting as a practising midwife and not as a maternity nurse

Living in period means a period being not less than 14 days nor more than 28 days after the end of labour during which the continued attendance of the midwife on the mother and child is requisite

### Disciplinary Investigations

If the secretary or other officer of a local medical committee assists a doctor in presenting his case under the Service Committees and Tribunal Regulations 1948, he is entitled to have copies of all the relevant documents. Provided that all the doctors concerned in the allegations agree, he should also be supplied with copies if he is present—as he is entitled to be—when the Medical Service Committee hears a case (Ministry of Health, ECL 101). A summary of these regulations appeared in the *Journal* of April 3 (p 653)

### Ambulance Service

Since local authorities generally have bulk supplies of petrol for running ambulances, they have no coupons for this purpose. On long journeys it may be necessary for the ambulances to refuel and local authorities are therefore asked (Ministry of Health Circular 165/48) to issue petrol in such cases from supplies controlled by them in connexion with any of their services, particularly from depots providing a 24 hour service—e.g. fire stations. Ambulances should, wherever possible, be supplied with commercial (red) petrol, but cars for sitting cases are private motor vehicles and should be fuelled with private petrol. The Minister of Fuel and Power has agreed that E coupons may be issued to all local authorities to facilitate the refuelling of sitting case cars on long journeys where there is not separate storage available for private petrol.

### Filling Vacancies

There should be no delay in consulting local medical committees about the selection of applicants (who must have completed form EC 16) to fill a vacancy, the Ministry of Health points out (ECL 100) to local executive councils. Delay might be minimized by each appointing a subcommittee. All application forms (Form EC 16) must be transmitted to the Medical Practices Committee (with relevant details and references) but where there has been more than one application to fill a particular vacancy the local executive council may, after consultation with the local medical committee, either (a) send with the forms a short list of those applicants thought to deserve special consideration or (b) arrange to interview a short list of candidates and make a specific recommendation to the Medical Practices Committee. The Medical Practices Committee prefers procedure (a). Reasons that have led the council and the local medical committee to support or not to support an application should be given for each candidate (on a form similar to Appendix 4 of ECL 14). The council should also give information about the district covered by the practice in so far as it has not already done so.

If a practice of a retired or deceased practitioner extended into more than one executive council area, the council area where the doctor resided should normally report the need for filling the vacancy but the councils for the other areas should also notify the Medical Practices Committee of the resignation or death. A successful applicant can apply for inclusion in the medical lists of any of those areas.

### Certificates under Education Act

A practitioner is required to issue to his NHS patients certain certificates free of charge. The provisional list issued by the Ministry includes certificates issued under the Education Act 1944 as evidence that a child was prevented from attending school by reason of sickness. In a recent circular to executive councils (ECL 101) the Minister states that he is advised that certificates can be regarded as required for this purpose only where a parent is summoned or is in risk of being summoned by the local education authority for failure to see that his child attends school. The matter will be reconsidered when the Inter Departmental Committee on Medical Certificates has reported.

## INSURANCE ACTS COMMITTEE

### CALL FOR REVISION OF REMUNERATION

A meeting of the Insurance Acts Committee was held on Nov 11, with Dr E A Gregg in the chair. The committee in a special resolution conveyed its thanks to Dr J W Bone for his long and outstanding services as treasurer of the National Insurance Defence Fund, an office which he has recently resigned.

Dr Dain, who had been nominated by the committee as a member of the Tribunal under Sect. 42 of the Act, explained that it had been intimated to him that it was undesirable that members of this Tribunal, on one side or the other, should be persons who had been prominently associated with the controversy relating to the Service. Moreover, cases which had been before the Tribunal might subsequently come before the General Medical Council, of which he was a member. Therefore he desired to withdraw his name. The committee appointed Dr A S Winstanley in Dr Dain's place.

Some critical discussion took place on the function of the Medical Practices Committee in regard to open and closed areas and the employment of assistants. These points will be raised with the Medical Practices Committee at the first opportunity.

### The Work and Income of Doctors

The committee received a report from the Remuneration Subcommittee which was appointed at its last meeting. This report stated that the principal grievance in the field of remuneration, apart from the apprehension arising from the first quarterly payment, came from doctors in small towns and semi rural areas where conditions were such that it was almost impossible to acquire a large list of public patients. Private practice had diminished to very small proportions, and this together with the increase in the volume of work and the prospect of worse conditions in the coming winter, had contributed to the unrest. A statement on the subject was issued to the Press on Oct 28 announcing that a report on the whole subject was being prepared for presentation to the Ministry.

Questions were raised as to Whitley Council machinery. The Secretary (Dr Charles Hill) stated that the point that the Whitley Council for the medical profession should be autonomous had been met. He thought the detailed proposals when they came forward would be found to be satisfactory as far as they went. It was likely that such matters as were now under discussion—namely, a review of remuneration in general—would still remain for direct discussion with the Ministry as a matter of major policy instead of coming within the routine of the Whitley machinery. What actually came within the scope of such machinery was a matter for discussion with the Ministry.

The view of the committee was that the position of practitioners with smaller lists who were not able to obtain adequate income was the first line of approach to be made and as a first step it should be pointed out that in so far as the number of general practitioners joining the Service was in excess of the figure of 17 900 (the figure of 19 400 was mentioned) upon which the calculation of the Central Practitioners Fund was based, a proportionate increase in that fund was necessary to implement the Spens Committee's recommendation. Other points for discussion were the adequacy of the Special Inducements Fund and the need for early and generous payment for mileage.

The question of basic salary entered into the discussion. The system under which the Minister decides appeals was criticized because it means that the Minister, who is not paying the additional moneys involved, is in the position of finally deciding the issue. It was decided to recommend that the appropriate regulations be amended so as to provide that the Medical Practices Committee or some central professional body is consulted by the Minister in all cases of appeal against decisions on basic salary.

### Maternity Medical Services

Among many other matters on the agenda of the committee were several concerning maternity medical services. It was

greed to take no action at the present stage to raise with the Ministry the general question of the fees for maternity medical services. The whole matter will be reviewed later in the light of experience. Practitioners who have been refused admission to the local obstetric list and seek advice as to their position are to be advised to reapply for admission to the list.

The committee could not accept the view, which the Minister had put forward, that treatment for a miscarriage should be regarded as part of the ordinary obligation of a general practitioner under his terms of service. On the subject of administration of anaesthetics in midwifery, it was agreed that the fee for the services of a second practitioner for this purpose, together with mileage when claimed, should be paid direct to that practitioner, also that representations should be made to the Ministry that there be provision for the payment of mileage for each visit at the rate of 1s a mile each way beyond the two mile radius.

Other decisions taken referred to the fees for administration of anaesthetics in dental cases where the patient is in the National Health Service (from 30s per administration, depending upon the length of the operation and the anaesthetic used, is the present B.M.A. policy), and the question of vaccination and immunization, which, it was agreed, formed no part of the practitioner's duty under his terms of service but was a statutory obligation on the local authority, for which the practitioner should be entitled to a separate fee. It was agreed to make representations to the Ministry to this effect.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley

## Questions Answered

We publish here the answers to a selection of questions that seem to be of general interest.

### Consultants Cannot Opt Out

**Q**—On what conditions can a consultant who has already made adequate provision for retirement by private insurance opt out of the Health Service superannuation scheme?

**A**—The option is not available to consultants but is limited to those doctors whose names were on the list of an executive council on July 5, 1948. Representations have been made to the Ministry that the option should be extended to consultants.

### Drugs and Appliances Required in Special Circumstances

**Q**—I have read the section in the Supplement headed "Prescribing in N.H.S. (Aug 21 p. 89) referring to supply to practitioners of drugs and appliances required in special circumstances. I should be glad to know whether the procedure for ordered appliances in England as well as Scotland and whether Form EC 10A is now obtainable from local executive councils for the use of Form EC 10A as an alternative to the payment of £12 per year per 100 patients for emergency drugs?

**A**—The statement in the Supplement relates to Scotland only. In Scotland a practitioner in the Service may order on Form EC 10A for stock purposes such drugs and appliances as he requires to supply "on the spot"—i.e., those required for immediate administration or application or for use before a prescription can be conveniently obtained by the patient on an ordinary prescription. In England and Wales a practitioner receives £25 6d per annum for every 100 persons on his

list excluding those to whom he has arranged or is required to supply all necessary drugs and prescribed appliances. Additional payment may be claimed where specially expensive drugs on the official list are used in emergencies. Form EC 10A cannot be used in England and Wales, the practitioner in this case obtains his emergency "stock" by direct purchase.

### Specialists and National Insurance

**Q**—I am a specialist in contract with two regional hospital boards for a total of eight sessions per week but am told that, for the purpose of National Insurance contributions, I am considered as a self-employed person. Why is this?

**A**—The regulations at the moment lay down that a specialist must be in contract with one authority (i.e., regional hospital board or board of governors of a teaching hospital) for at least six sessions per week if he or she is to be considered as an "employed person". Representations are being made to the Ministry on this point. Amendment of the regulations will be necessary to adjust the matter.

### Medical Practices Committee Expenses

**Q**—Is part of the capitation fee deducted for payment of the expenses of the Medical Practices Committee?

**A**—No part of the capitation fee is deducted for the expenses of the Medical Practices Committee. All expenses incurred by or in respect of this committee are paid by the Government.

## HEARD AT HEADQUARTERS

### Lord Horder's Meeting

The Caxton Hall meeting fully came up to expectations. Six hundred doctors were expected, and one count gave 673 attending, but many came late and had to stand during the proceedings or even invade the platform, and the number must have been well over 700. Lord Horder described himself as a realist. The Minister of Health, speaking to a common friend, had described him as an incontinent romanticist; he accepted the adjective but not the noun. The meeting was free from attacks on the B.M.A., and indeed among those who spoke during the afternoon were five members of the Association Council, while three of these five and two other members of the Council were elected as officers or committee men. One speaker wanted to divide the sheep from the goats; he was prepared to receive into the Fellowship those working in the Service, but only on condition that they donned the white sheet, but the meeting would have none of such distinctions. The word "Fellowship" as the title of the new organization is not entirely happy. It suggests something academic or social, whereas the new body is a crusade or at least a garrison. But "Association" was evidently considered to have a rivalry aspect about it, "Guild," which Lord Horder favoured, would have required a legal charter to make it effective, and "Council" suggested a closed body.

### Students in Assembly

The President of the Association gave a charming little address in presenting the Association's student prizes at the annual conference of the B.M.S.A. last week. Sir Lionel Whitby took occasion to remind the students that the B.M.A. is not a trade union dressed up as something else, nor is it wholly a political organization charged with wringing the best contracts for doctors out of an unwilling Government. It has other activities whose value must not be measured by the space they occupy in the news. He said that the Association had probably the finest medical publishing service in the world, its journals and abstracts were some of the greatest contributions to scientific medicine, and its Divisions, with their scientific meetings, were a splendid means of encouraging such an outlook among men in practice. At the same meeting the students had the privilege of listening to Dr W. N. Pickles, who spoke of the opportunities of general practice. Dr Pickles is famous as a clinical observer, and he gave a number of his experiences as a country doctor, but what was most inspiring

the talk was his description of the way he encountered patients and looked after them in the good old tradition of a family doctor

### The Patient's Consent

There has recently been another instance of a doctor examining a patient without the patient's consent. An injured workman employed by a firm was being attended by his own doctor in a hospital. The employers' solicitor asked the doctor to examine the patient on the employers' behalf and report on his condition. The doctor did so without explaining to the patient the significance of the examination or obtaining his consent to send a report. The patient probably regarded the examination as a routine one in the course of treatment. Subsequently an organization acting on behalf of the patient also asked the doctor for a report on his injury, and the doctor replied that he was unable to do it because he had already given a report to the other side. The legal traps in medical practice are numerous and intricate, and this is one that should always be borne in mind. No report should ever be given without the consent of the patient. Where there is any possibility of doubt consent should be obtained in writing in the presence of disinterested witnesses. The problem was discussed in an article in the *Journal* of April 24 (p. 801). Where an examination is required, as in this case, for the other side, the injured man or his solicitor should have the opportunity of arranging for a medical man to be present at the examination for the express purpose of representing the patient's interests.

### COUNCIL ON WELFARE OF HANDICAPPED PERSONS

The Secretary of State for Scotland has appointed a Council of nineteen members to advise him on matters pertaining to the welfare of handicapped persons with particular reference to the provisions of the National Assistance Act. The Act gives local authorities power to make arrangements for promoting the welfare of persons who are blind, deaf, or dumb, and other persons who are substantially and permanently handicapped by illness, injury or congenital deformity.

Local authorities have for long had a duty to provide for the welfare of the blind, but they have not had specific statutory powers to provide for the general welfare of other severely disabled persons. A new field of local authority endeavour has therefore to be opened up, and it will be the main function of the new Council to give the Secretary of State such advice as will enable him to guide local authorities in the preparation of satisfactory schemes.

The Council consists of the following: The Hon. Lord Stevenson, K.C. (Chairman), Mr. Charles H. W. G. Anderson, Head Master, Royal Blind School, Edinburgh; Mr. W. Veitch Anderson, F.R.C.S. Ed., Edinburgh; Mr. David S. Brown, Councillor, Glasgow Corporation; Miss C. D. Hamilton Bruce, Warden, Trefoil School for Handicapped Children, Whitburn; Mr. James Cormack, Superintendent, Edinburgh and South East of Scotland Society for the Blind; Professor T. Ferguson, Professor of Hygiene, Glasgow University; the Reverend J. A. Fisher, Convener, Kirkcudbright County Council; Mr. James Forde, J.P., Councillor, Ayr County Council; Mr. D. Kennedy Fraser, Psychologist and Master of Method, Jordonhill College, Glasgow; Dr. J. G. M. Hamilton, Edinburgh; Mr. James Hutcheon, J.P., Town Clerk, Dumfries; Mr. D. L. McIntosh, late Superintendent, Glasgow School for the Deaf; Mrs. David Mackenzie, Honorary Secretary to the Scottish Orthopaedic Council; Mr. Duncan R. Matheson, Councillor, Edinburgh Town Council; Mr. T. R. Millar, Councillor, Clackmannan County Council; Lord Provost J. Ure Primrose, Perth; Mr. John Robertson, Welfare Services Officer, Stirling; the Reverend W. H. Wood, Honorary Secretary of the Scottish Association for the Deaf; Mr. R. I. Hulle, Department of Health for Scotland (Secretary).

The Minister of Health has made the following appointments to regional hospital boards—*North West Metropolitan*: Dr. W. J. T. Kimber, Medical Superintendent of Hill End Hospital, St. Albans, in succession to Dr. J. R. Rees; *Welsh*: Mr. E. K. Roy Thomas, Senior Ophthalmic Surgeon to the Swansea General and Eye Hospital, in succession to Dr. J. Lloyd Davies; *Welsh*: Mr. J. T. Morrison, Dean of the Faculty of Medicine, University of Liverpool, in succession to Professor Davie; Mr. Morrison is also a member of the Liverpool Regional Hospital Board.

## Correspondence

### The Distinction Awards

SIR—The idea of distinction awards for consultants is advocated by the Spens Committee has had an unfavourable reception in the profession. Now that the Government has decided to set up a committee to advise them on the disposal of these awards the whole question merits more public discussion than it has yet had. The arguments against these awards are easy to see. The task of the Selection Committee will be so difficult that errors and omissions must necessarily occur. There is a risk that notoriety will be rewarded rather than distinction; that industry may be overlooked in the quest of brilliance; that the back-room boys will be forgotten at the prize giving; and the provincial consultant long accustomed to his mute inglorious state must now expect impoverishment as well. Resentment and envy, it is said, will be created among hospital staffs where happy harmony hitherto existed. The work of the disappointed man will be depressed by his exclusion while the successful aspirant, having reached the haven, will rest on his oars.

There are, however, other aspects of these glittering prizes which should be considered. They provide at the same time both a reward and an incentive which it may be difficult to supply in any other way. They permit an escape from the flat rate of pay which means the permanent establishment of mediocrity. Without them salary increases would be dependent only on seniority, for the individualistic nature of the clinician's work makes a pyramidal system of promotion undesirable and indeed impracticable. They make it possible to assess the rewards of individual specialists without making invidious regulations concerning, for example, the relative values of the neurosurgeon and his anaesthetist.

They declare, and this is a notable admission, that even a Socialist Government believes in the necessity for an unequalitarian society. They provide for the professional man the antecedent golden carrot of which the employer and employed have been largely dispossessed. They declare that important as idealism, unselfishness, sense of duty, pride of craftsmanship and creative enthusiasm are, they cannot be counted on to stimulate all the people all the time to their optimum performance.

It is probable that the obvious difficulties in application of these awards may be mitigated by reason and good will. Those who continue to oppose them have the duty to provide an answer to two questions: (1) How else, in a profession whose remuneration is largely to be determined by fixed annual increments, are you to provide incentive for effort and reward for performance? (2) How else are you to discriminate in financial terms between the value of the different specialties?—I am, etc.,

Derby

### Basic Salary

SIR—I am in practice in a small market town 14 miles from Oxford and have applied for the basic salary to tide over these difficult times. I have received a letter from the local Local Medical Committee saying that they had received instructions from the Oxford Local Medical Committee 'to assess my claim for the basic salary and pass on any evidence to the Oxford Local Medical Committee that they get from me during the inquisition in support of my claim.' In other words my professional neighbours down the road or up the road, are to poke into my private affairs and—it just won't do. I take a very poor view of all this and in what an invidious position to place the local Local Medical Committee! Still, that is their headache. I suppose that even the satisfaction derived from exercising the most local of authorities must have some qualifications—I am etc.

Thame, Oxon.

E. GRANGER

SIR—Now that the political implications of the universal basic salary have been removed it is disturbing to find that in some quarters, including the B.M.A., a stigma still attaches to its legitimate use by the lower-income groups. While it is true that the result of successfully claiming the £300 is a lowering

of the capitation fee for those doctors who are able—and willing—to take on big numbers, it might have been more fitting for the B.M.A. to have urged those less unfortunate doctors to accept without murmuring a deduction which helps those who have been hardest hit than to discourage those unfortunates from improving their lot by the agreed method of claiming the basic salary.

I have not seen it urged that doctors should refrain from making the most of their practice incomes for compensation purposes because by so doing they were lowering the average payment from the fixed pool, though this is equally true. Surely a doctor with less than 2,000 State patients has a duty on behalf of his family, his creditors, and his guarantors to claim the £300 to help to minimize his losses. Let those with lists of 2,000+ be stimulated to protest against the inadequacy of the proposed capitation fee rather than blame their colleagues for their efforts at survival—I am, etc.,

### Locumtenents and Successors

SIR—May I bring to your notice two important points which appear to have been overlooked up till now in the discussions on the new Health Service—viz, the position of doctors doing locumtenent work, and the methods employed in the selection by the various executive committees of the doctors to succeed to practices becoming vacant either by death or retirement.

(1) *Locumtenents*—The position of these individuals does not appear to have been given any consideration whatsoever so far yet the provision of locums for holidays, sickness, death vacancies and postgraduate work must surely be considered a very important cog in a smooth running service. In the past they were provided, often somewhat unsatisfactorily from both points of view, either by one of the various medical agencies or through one of the large drug houses. If the new service is not to belie its name something much more serviceable and satisfactory must be evolved. The doctor in practice should be entitled to expect that, at a moment's notice, he can be provided with a reasonably efficient and experienced locum, and the public the same. Locums should no longer be recruited mainly from the ranks of recently qualified, comparatively inexperienced doctors. There is surely a very definite scope for a National Health locum service, staffed by doctors who are willing to do this type of work and qualified by both hospital and general practice experience to do so. Only doctors who can satisfy the above desiderata should be enrolled on such a list, and they would be expected to accept any post within a reasonably wide radius from their headquarters.

As they are expected to undertake the work of doctors considered capable of running large practices, this class of locum should be selected and paid accordingly, preferably a fairly high salary with, possibly, pension rights, which would encourage recruitment to such a service and the desire to remain in it for a reasonable spell. Alternatively, a basic salary could be paid to cover out-of-work periods plus fees while actually working. Admission to such a roll would have to involve signing on for a minimum period and agreement to undertake any such work allotted.

Obviously such a locum would have to be paid even when not working though workless periods would probably be short. The remuneration offered would have to include car allowance. The Service could at least partially reimburse itself from fees paid by the locum requiring the locum, such fees to depend on the income and location of the practice, and not a standard fee as in the past. The percentage of the amount of work involved or the desirability or otherwise of the locality. Incidentally, the current locum fee of 10 guineas weekly, plus board and lodging should be viewed in a proper perspective. It seems to the doctor paying it a reasonable fee but does not take into consideration the workless periods between locums sometimes of weeks duration, but almost invariably a few days with often one day's travelling unpaid for if the locum is away, and if a car is required an allowance of only two guineas weekly to cover tax, insurance, upkeep, and depreciation. A deduction of 5% agency fees and incidental expenses such as telephone and telegraph fees, postages, etc.

It is necessary to sketch a somewhat sketchy outline but I think some of the points will have to be very seriously considered especially if a new type of medical personnel develops which appears not

(2) *Successors to Practices*—The retiring doctor is now no longer faced with the choice of his successor, or but little. The public is faced with the choice of the most important, and if any lay person is asked the choice no doubt common sense would make him choose the best qualified to serve him. Unfortunately, as there is no such guarantee can be given. Applicants are expected to be expected to make tentative arrangements

for housing and surgery accommodation before they know even whether they are short-listed for the post. In their application they have to fill in the address from which they propose to practise and their hours of consultation, which seems to be expecting a good deal. Obviously a candidate with local knowledge or influence is in a much more favourable position than his competitor living at a distance. Also one with capital at command sufficient to satisfy the present inflated cost of housing will no doubt be considered more favourably by a selection committee than one less well endowed, as the housing question is so important and a fairly quick choice must be made.

Such considerations as the above, however, are surely not the likeliest to give the aforesaid layman and potential patient the doctor of his choice, yet I venture to suggest that, as in the old "bad" days of buying and selling practices, they will be paramount unless some means can be adopted whereby all candidates are placed on the same footing. In this connexion, financial help for the purchase of premises, or actual purchase by the State itself, suggest themselves. Final selection should be purely on merit. Only thus can our future G.P.s feel that they are getting a fair deal, and the public, through their representatives, be given a fair choice.

### Supply of Nitrous Oxide Gas

SIR—The attention of the National Birthday Trust Fund has been drawn to the confusion which appears to exist about the supply to general practitioners of cylinders of nitrous oxide gas for analgesic purposes in maternity cases under the National Health Service. As the Trust is particularly interested in the provision of analgesia to women confined in their own homes, approach was made to the Ministry of Health for official guidance in the matter. I quote from the reply received from an official of the Ministry in case this authoritative statement may be of interest.

"The position is that, if a doctor is engaged by the patient to give maternity medical service under Part IV of the Act, he is in the same position as any doctor giving general medical service under Part IV. He may write prescriptions or may himself supply any drug 'personally administered'—e.g., nitrous oxide. For drugs so supplied he will receive payment from the executive council on presentation of a claim on E.C. 10 to the executive council."

"If the doctor is called in by a midwife in emergency, he is not giving maternity medical service under Part IV of the National Health Service Act, but is giving services under the Midwives Act, 1918. He receives a fee which includes the supply of necessary drugs and dressings, except that he gets extra payment for certain expensive drugs named in Part 2 of the Schedule to S.I. 1453 of 1948. In such cases the patient would have a midwife in attendance, and, as you know, midwives are supplied by the local health authority with cylinders of nitrous oxide. Many, but not all, doctors have cylinders, but some may not have realized that when giving maternity service under Part IV they can be paid for any nitrous oxide they supply themselves."

—I am, etc.

Secretary

### Basic Salary for All Principals

SIR—The latest arrangement for the payment of basic salaries to general practitioners is so thoroughly bad that I am astonished at the profession acquiescing without vigorous protest and even without general discussion. Presumably bowing to B.M.A. pressure, the Minister of Health, so often accused of intransigence, has reduced the basic salary to a mere charitable contribution paid by the profession after scrutiny of the applicants' private affairs. One can well understand the bitterness and dissension which are already felt and which are likely to be perpetuated. Many who were strongly opposed to the conception of basic salary are now advocating an alternative system of payment by sliding scale, such as suggested by Dr. M. K. Dorothy Douglas (*Supplement* Oct 30 p. 154). With either method the large practices must inevitably subsidize the small ones, but I contend the sliding-scale system would involve a most inequitable division of the local pool.

Surely the heat of political controversy has blinded our representatives to the merits of the original proposal of a universal basic salary. There are many cogent arguments in favour of using this method in the division of the local pool.

is were done voluntarily in each executive council area there need be no fear of the control or manipulation of the salary which caused opposition to the idea of a salary from the Government. In a community of 288 000 and per person would give £300 and thus if all the principals in the area say 120, took the £300 basic salary it would amount to a first charge on the local pool equivalent to 2s 6d of the capitation fee. The remainder, of course, would be distributed according to the numbers on each doctor's list. The only reservation necessary would be that the salary could be withheld from any doctor who in the judgment of his colleagues was not taking an active and fair share of the medical work in the area.

The advantages of such a scheme might be summarized as follows: (1) It is the most equitable method of subsidizing the small practices by the large. (2) It would promote that professional unity which is more than ever necessary. (3) It would encourage group practice. (4) It would mitigate that type of competition for patients in which clinical ability plays no part. (5) By giving a measure of independence it would facilitate more impartial and therefore more accurate certification. (6) It reconciles as far as may be the two conflicting needs of helping the small practices on one hand and providing equal pay for equal work on the other. I am absolutely opposed to the present scheme and equally so to that of a sliding scale. My suggestion is that there should be a basic salary for every active principal, if not, then for no one—I am, etc.

### Flagrant Abuses

SIR,—Certain flagrant abuses of the National Health Service should be brought to the public notice. On several occasions patients, having arrived at the surgery to find a considerable number ahead of them, have returned home to telephone for a visit. Later they have actually confessed that they could not face the long queue, and thus saw nothing wrong in their subsequent action. One patient—incredibly—reported that he had a high temperature in order to get a visit, he admitted on opening his front door that his temperature was normal and that his message was a ruse to save himself the trouble of waiting in the surgery. Again, another patient who sent in a message after 1 p.m. had to be visited three times before she was at home to receive her doctor. Her complaint was trivial.

We strongly urge that the public should be warned against these abuses of the Health Service if they wish for its success. They must accept the inconveniences as well as the advantages of the service. Let the public treat us fairly and with common sense and we in turn will do our best for them.—We are, etc.,

### NHS Remuneration

SIR—I wish to thank Dr Charles Hill for his circular letter (Supplement, Oct 23, p 145) which explains why we were underpaid on Oct 1. It should, however, be pointed out to the Minister that doctors, like postmen or miners or any other working men, do not live from year to year but from day to day. This is more especially the case since the advent of this Government, which has taxed almost every conceivable commodity in daily use—e.g., beer, tobacco and filing cabinets for medical cards. It is therefore more than ever desirable that our quarterly remuneration should approximately be the amount which we rightly expect.

Even if the correct estimated payment had been made, it would appear that the medical profession has been sold a particularly unpleasant mongrel pup, for we have been—if we are not to bandy words—forced to yield our right to buy or sell our own practice goodwill. We have been forced to cede our inherent right to practise wherever we may wish and have thus become the puppets of the Medical Practices Committee. We must stay put or starve or put in interminable applications for practices with so little knowledge of the pertinent facts that by comparison a gamble on the "pools" seems a certainty.

Our work has without question increased and our pay diminished in proportion to the 'enthusiastic co-operation' we have shown in entering the scheme. For example, we are to be paid on the assumption of a 95% population risk. This assumes a 5% income from private practice. In my case the proportion of public patients

to private is 99.95% to 0.05%. (Prior to July 5 this proportion was 60/40 and income 50/50.) Thus, largely due to my enthusiasm asked for by the Minister, I am losing on both the swings and the roundabouts, and I know that my lot is not singular. But there does not appear to be any undue haste on the part of the Minister to reciprocate the 'enthusiastic co-operation'. In my view something will have to be done and done quickly by the profession, the General Medical Services Committee (who are avowedly acting on our behalf) and the Minister to ameliorate our pay and conditions of service in order to bring some sense of proportion into the scheme of things.

First the Spens Report must be implemented retrospectively from July 5. Secondly, if no other means is available, a fee will have to be charged per attendance to check abuses. In any case, it seems clear to me that the general practitioners cannot continue to honour the Minister's blank cheques on our services unless the Minister for his part hastens to honour his promises in the manner suggested and so make the reward more nearly fitting to the work than that received in October.—I am, etc.

PEPPI J GONSALVES

### Inadequate Remuneration

SIR,—The fact that the basic salary is to become a subsidy on the practitioners of the area has come as a great surprise to many of us, and we are beginning to wonder where the deductions from the already inadequate capitation will end. The document recently circulated giving an explanation of how the Practitioners' Fund is distributed may be a very clever treatise in higher mathematics, but it cuts no ice with practitioners who are attempting to carry out their obligations conscientiously. It is time the B.M.A. gave up chasing the shadows and got down to the job of seeing that its members are adequately remunerated. The Negotiating Committee was I believe, elected for this purpose, they should waste no more time and get on with it.—I am, etc.,
